

# Package ‘rtables’

May 25, 2023

**Title** Reporting Tables

**Version** 0.6.1

**Date** 2023-05-04

**Description** Reporting tables often have structure that goes beyond simple rectangular data. The 'rtables' package provides a framework for declaring complex multi-level tabulations and then applying them to data. This framework models both tabulation and the resulting tables as hierarchical, tree-like objects which support sibling sub-tables, arbitrary splitting or grouping of data in row and column dimensions, cells containing multiple values, and the concept of contextual summary computations. A convenient pipe-able interface is provided for declaring table layouts and the corresponding computations, and then applying them to data.

---

|               |   |
|---------------|---|
| add_colcounts | <i>Add the column population counts to the header</i> |
|---------------|---|

---

**Description**

Add the data derived column counts.

**Usage**

```
add_colcounts(lyt, format = "(N=xx)")
```

**Arguments**

lyt layout object pre-data used for tabulation

format FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.

**Details**

It is often the case that the the column counts derived from the input data to build\_table is not representative of the population counts. For example, if events are counted in the table and the header should display the number of subjects and not the total number of events. In that case use the col\_count argument in build\_table to control the counts displayed in the table header.

**Value**

A PreDataTableLayouts object suitable for passing to further layouting functions, and to build\_table.

**Author(s)**

Gabriel Becker

**Examples**

```
lyt <- basic_table() %>% split_cols_by("ARM") %>%
  add_colcounts() %>%
  split_rows_by("RACE", split_fun = drop_split_levels) %>%
  analyze("AGE", afun = function(x) list(min = min(x), max = max(x)))
lyt

tbl <- build_table(lyt, DM)
tbl
```

---

|                 |  |
|-----------------|--|
| add_combo_facet | <i>Add a combination facet in postprocessing</i> |
|-----------------|--|

---

**Description**

Add a combination facet during postprocessing stage in a custom split fun.

**Usage**

```
add_combo_facet(name, label = name, levels, extra = list())

add_overall_facet(name, label, extra = list())
```

**Arguments**

|        |  |
|--------|--|
| name   | character(1). Name for the resulting facet (for use in pathing, etc).                        |
| label  | character(1). Label for the resulting facet.   |
| levels | character. Vector of levels to combine within the resulting facet.                           |
| extra  | list. Extra arguments to be passed to analysis functions applied within the resulting facet. |

**Details**

For `add_combo_facet`, the data associated with the resulting facet will be the data associated with the facets for each level in `levels`, rbound together. In particular, this means that if those levels are overlapping, data that appears in both will be duplicated.

**Value**

a function which can be used within the `post` argument in `make_split_fun`.

**See Also**

[make\\_split\\_fun](#)

Other `make_custom_split`: [drop\\_facet\\_levels\(\)](#), [make\\_split\\_fun\(\)](#), [make\\_split\\_result\(\)](#), [trim\\_levels\\_in\\_facets\(\)](#)

**Examples**

```
mysplfun <- make_split_fun(post = list(add_combo_facet("A_B", label = "Arms A+B",
                                                levels = c("A: Drug X", "B: Placebo")),
                             add_overall_facet("ALL", label = "All Arms")))

lyt <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM", split_fun = mysplfun) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
```

---

`add_existing_table`      *Add an already calculated table to the layout*

---

**Description**

Add an already calculated table to the layout

**Usage**

```
add_existing_table(lyt, tt, indent_mod = 0)
```

## Arguments

|            |  |
|------------|--|
| lyt        | layout object pre-data used for tabulation   |
| tt         | TableTree (or related class). A TableTree object representing a populated table.   |
| indent_mod | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior. |

## Value

A PreDataTableLayouts object suitable for passing to further layouting functions, and to `build_table`.

## Author(s)

Gabriel Becker

## Examples

```
lyt1 <- basic_table() %>%
  split_cols_by("ARM") %>%
  analyze("AGE", afun = mean, format = "xx.xx")

tbl1 <- build_table(lyt1, DM)
tbl1

lyt2 <- basic_table() %>% split_cols_by("ARM") %>%
  analyze("AGE", afun = sd, format = "xx.xx") %>%
  add_existing_table(tbl1)

tbl2 <- build_table(lyt2, DM)
tbl2

table_structure(tbl2)
row_paths_summary(tbl2)
```

---

|                 |                           |
|-----------------|---------------------------|
| add_overall_col | <i>Add Overall Column</i> |
|-----------------|---------------------------|

---

## Description

This function will *only* add an overall column at the *top* level of splitting, NOT within existing column splits. See [add\\_overall\\_level](#) for the recommended way to add overall columns more generally within existing splits.

## Usage

```
add_overall_col(lyt, label)
```

**Arguments**

lyt                    layout object pre-data used for tabulation  
 label                character(1). A label (not to be confused with the name) for the object/structure.

**Value**

A PreDataTableLayouts object suitable for passing to further layouting functions, and to build\_table.

**See Also**

[add\\_overall\\_level\(\)](#)

**Examples**

```
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  add_overall_col("All Patients") %>%
  analyze("AGE")
lyt

tbl <- build_table(lyt, DM)
tbl
```

---

add\_overall\_level        *Add an virtual 'overall' level to split*

---

**Description**

Add an virtual 'overall' level to split

**Usage**

```
add_overall_level(
  valname = "Overall",
  label = valname,
  extra_args = list(),
  first = TRUE,
  trim = FALSE
)
```

**Arguments**

valname                character(1). 'Value' to be assigned to the implicit all-observations split level. Defaults to "Overall"  
 label                character(1). A label (not to be confused with the name) for the object/structure.

|            |  |
|------------|--|
| extra_args | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function. |
| first      | logical(1). Should the implicit level appear first (TRUE) or last FALSE. Defaults to TRUE.   |
| trim       | logical(1). Should splits corresponding with 0 observations be kept when tabulating.   |

**Value**

a closure suitable for use as a splitting function (splfun) when creating a table layout

**Examples**

```
lyt <- basic_table() %>%
  split_cols_by("ARM", split_fun = add_overall_level("All Patients",
                                                    first = FALSE)) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
tbl

lyt2 <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("RACE",
                split_fun = add_overall_level("All Ethnicities")) %>%
  summarize_row_groups(label_fstr = "%s (n)") %>%
  analyze("AGE")
lyt2

tbl2 <- build_table(lyt2, DM)
tbl2
```

---

all\_zero\_or\_na      *Trimming and Pruning Criteria*

---

**Description**

Criteria functions (and constructors thereof) for trimming and pruning tables.

**Usage**

```
all_zero_or_na(tr)

all_zero(tr)
```

```

content_all_zeros_nas(tt, criteria = all_zero_or_na)

prune_empty_level(tt)

prune_zeros_only(tt)

low_obs_pruner(min, type = c("sum", "mean"))

```

### Arguments

|          |  |
|----------|--|
| tr       | TableRow (or related class). A TableRow object representing a single row within a populated table.   |
| tt       | TableTree (or related class). A TableTree object representing a populated table.   |
| criteria | function. Function which takes a TableRow object and returns TRUE if that row should be removed. Defaults to <a href="#">all_zero_or_na</a>                    |
| min      | numeric(1). ( <code>low_obs_pruner</code> only). Minimum aggregate count value. Subtables whose combined/average count are below this threshold will be pruned |
| type     | character(1). How count values should be aggregated. Must be "sum" (the default) or "mean"   |

### Details

`all_zero_or_na` returns TRUE (and thus indicates trimming/pruning) for any *non-LabelRow* TableRow which contain only any mix of NA (including NaN), 0, Inf and -Inf values.

`all_zero` returns TRUE for any non-Label row which contains only (non-missing) zero values.

`content_all_zeros_nas` Prunes a subtable if a) it has a content table with exactly one row in it, and b) `all_zero_or_na` returns TRUE for that single content row. In practice, when the default summary/content function is used, this represents pruning any subtable which corresponds to an empty set of the input data (e.g., because a factor variable was used in [split\\_rows\\_by](#) but not all levels were present in the data).

`prune_empty_level` combines `all_zero_or_na` behavior for TableRow objects, `content_all_zeros_nas` on `content_table(tt)` for TableTree objects, and an additional check that returns TRUE if the tt has no children.

`prune_zeros_only` behaves as `prune_empty_level` does, except that like `all_zero` it prunes only in the case of all non-missing zero values.

`low_obs_pruner` is a *constructor function* which, when called, returns a pruning criteria function which will prune on content rows by comparing sum or mean (dictated by `type`) of the count portions of the cell values (defined as the first value per cell regardless of how many values per cell there are) against `min`.

### Value

A logical value indicating whether `tr` should be included (TRUE) or pruned (FALSE) during pruning.

**See Also**

[prune\\_table\(\)](#), [trim\\_rows\(\)](#)

**Examples**

```
adsl <- ex_adsl
levels(adsl$SEX) <- c(levels(ex_adsl$SEX), "OTHER")
adsl$AGE[adsl$SEX == "UNDIFFERENTIATED"] <- 0
adsl$BMRKR1 <- 0

tbl_to_prune <- basic_table() %>%
  analyze("BMRKR1") %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX") %>%
  summarize_row_groups() %>%
  split_rows_by("STRATA1") %>%
  summarize_row_groups() %>%
  analyze("AGE") %>%
  build_table(adsl)

tbl_to_prune %>% prune_table(all_zero_or_na)

tbl_to_prune %>% prune_table(all_zero)

tbl_to_prune %>% prune_table(content_all_zeros_nas)

tbl_to_prune %>% prune_table(prune_empty_level)

tbl_to_prune %>% prune_table(prune_zeros_only)

min_prune <- low_obs_pruner(70, "sum")
tbl_to_prune %>% prune_table(min_prune)
```

---

analyze

*Generate Rows Analyzing Variables Across Columns*

---

**Description**

Adding *analyzed variables* to our table layout defines the primary tabulation to be performed. We do this by adding calls to `analyze` and/or `analyze_colvars` into our layout pipeline. As with adding further splitting, the tabulation will occur at the current/next level of nesting by default.

**Usage**

```
analyze(
  lyt,
  vars,
  afun = simple_analysis,
```

```

var_labels = vars,
table_names = vars,
format = NULL,
na_str = NA_character_,
nested = TRUE,
inclNAs = FALSE,
extra_args = list(),
show_labels = c("default", "visible", "hidden"),
indent_mod = 0L,
section_div = NA_character_
)

```

### Arguments

|             |  |
|-------------|--|
| lyt         | layout object pre-data used for tabulation   |
| vars        | character vector. Multiple variable names.   |
| afun        | function. Analysis function, must take x or df as its first parameter. Can optionally take other parameters which will be populated by the tabulation framework. See Details in <a href="#">analyze</a> .  |
| var_labels  | character. Variable labels for 1 or more variables   |
| table_names | character. Names for the tables representing each atomic analysis. Defaults to var.  |
| format      | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| na_str      | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".  |
| nested      | boolean. Should this layout instruction be applied within the existing layout structure <i>if possible</i> (TRUE, the default) or as a new top-level element ('FALSE). Ignored if it would nest a split underneath analyses, which is not allowed.               |
| inclNAs     | boolean. Should observations with NA in the var variable(s) be included when performing this analysis. Defaults to FALSE   |
| extra_args  | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function. |
| show_labels | character(1). Should the variable labels for corresponding to the variable(s) in vars be visible in the resulting table.   |
| indent_mod  | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.                 |
| section_div | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |

## Details

When non-NULL `format` is used to specify formats for all generated rows, and can be a character vector, a function, or a list of functions. It will be repped out to the number of rows once this is known during the tabulation process, but will be overridden by formats specified within `rcell` calls in `afun`.

The analysis function (`afun`) should take as its first parameter either `x` or `df`. Which of these the function accepts changes the behavior when tabulation is performed.

- If `afun`'s first parameter is `x`, it will receive the corresponding subset *vector* of data from the relevant column (from `var` here) of the raw data being used to build the table.
- If `afun`'s first parameter is `df`, it will receive the corresponding subset *data.frame* (i.e. all columns) of the raw data being tabulated

In addition to differentiation on the first argument, the analysis function can optionally accept a number of other parameters which, *if and only if* present in the formals will be passed to the function by the tabulation machinery. These are as follows:

**.N\_col** column-wise N (column count) for the full column being tabulated within

**.N\_total** overall N (all observation count, defined as sum of column counts) for the tabulation

**.N\_row** row-wise N (row group count) for the group of observations being analyzed (ie with no column-based subsetting)

**.df\_row** data.frame for observations in the row group being analyzed (ie with no column-based subsetting)

**.var** variable that is analyzed

**.ref\_group** data.frame or vector of subset corresponding to the `ref_group` column including subsetting defined by row-splitting. Optional and only required/meaningful if a `ref_group` column has been defined

**.ref\_full** data.frame or vector of subset corresponding to the `ref_group` column without subsetting defined by row-splitting. Optional and only required/meaningful if a `ref_group` column has been defined

**.in\_ref\_col** boolean indicates if calculation is done for cells within the reference column

**.spl\_context** data.frame, each row gives information about a previous/'ancestor' split state. see below

## Value

A `PreDataTableLayouts` object suitable for passing to further layouting functions, and to `build_table`.

## .spl\_context Details

The `.spl_context` data.frame gives information about the subsets of data corresponding to the splits within-which the current `analyze` action is nested. Taken together, these correspond to the path that the resulting (set of) rows the analysis function is creating, although the information is in a slightly different form. Each split (which correspond to groups of rows in the resulting table), as well as the initial 'root' "split", is represented via the following columns:

**split** The name of the split (often the variable being split in the simple case)

**value** The string representation of the value at that split

**full\_parent\_df** a dataframe containing the full data (ie across all columns) corresponding to the path defined by the combination of `split` and `value` of this row *and all rows above this row*

**all\_cols\_n** the number of observations corresponding to this row grouping (union of all columns)

**(row-split and analyze contexts only) <1 column for each column in the table structure** These list columns (named the same as `names(col_exprs(tab))`) contain logical vectors corresponding to the subset of this row's `full_parent_df` corresponding to that column

**cur\_col\_subset** List column containing logical vectors indicating the subset of that row's `full_parent_df` for the column currently being created by the analysis function

**cur\_col\_n** integer column containing the observation counts for that split

*note Within analysis functions that accept `.spl_context`, the `all_cols_n` and `cur_col_n` columns of the dataframe will contain the 'true' observation counts corresponding to the row-group and row-group x column subsets of the data. These numbers will not, and currently cannot, reflect alternate column observation counts provided by the `alt_counts_df`, `col_counts` or `col_total` arguments to `build_table`*

## Note

None of the arguments described in the Details section can be overridden via `extra_args` or when calling `make_afun`. `.N_col` and `.N_total` can be overridden via the `col_counts` argument to `build_table`. Alternative values for the others must be calculated within `afun` based on a combination of extra arguments and the unmodified values provided by the tabulation framework.

Gabriel Becker

## Examples

```
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  analyze("AGE", afun = list_wrap_x(summary) , format = "xx.xx")
lyt

tbl <- build_table(lyt, DM)
tbl

lyt2 <- basic_table() %>%
  split_cols_by("Species") %>%
  analyze(head(names(iris), -1), afun = function(x) {
    list(
      "mean / sd" = rcell(c(mean(x), sd(x)), format = "xx.xx (xx.xx)"),
      "range" = rcell(diff(range(x)), format = "xx.xx")
    )
  })
lyt2
```

```
tbl2 <- build_table(lyt2, iris)
tbl2
```

  child_names = var,
  cvar = "",
  section_div = NA_character_
)
```

### Arguments

|                           |  |
|---------------------------|--|
| <code>var</code>          | string, variable name  |
| <code>split_label</code>  | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).  |
| <code>afun</code>         | function. Analysis function, must take <code>x</code> or <code>df</code> as its first parameter. Can optionally take other parameters which will be populated by the tabulation framework. See Details in <a href="#">analyze</a> .  |
| <code>defrowlab</code>    | character. Default row labels if they are not specified by the return value of <code>afun</code>   |
| <code>cfun</code>         | list/function/NULL. tabulation function(s) for creating content rows. Must accept <code>x</code> or <code>df</code> as first parameter. Must accept <code>labelstr</code> as the second argument. Can optionally accept all optional arguments accepted by analysis functions. See <a href="#">analyze</a> . |
| <code>cformat</code>      | format spec. Format for content rows   |
| <code>split_format</code> | FormatSpec. Default format associated with the split being created.  |
| <code>split_na_str</code> | character. NA string vector for use with <code>split_format</code> .   |
| <code>inclNAs</code>      | boolean. Should observations with NA in the <code>var</code> variable(s) be included when performing this analysis. Defaults to FALSE  |
| <code>split_name</code>   | string. Name associated with this split (for pathing, etc)   |
| <code>extra_args</code>   | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function.   |

|              |  |
|--------------|--|
| indent_mod   | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.   |
| label_pos    | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| cvar         | character(1). The variable, if any, which the content function should accept. Defaults to NA.  |
| .payload     | Used internally, not intended to be set by end users.  |
| child_labels | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.  |
| child_names  | character. Names to be given to the sub splits contained by a compound split (typically a AnalyzeMultiVars split object).  |
| section_div  | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |

**Value**

An AnalyzeVarSplit object.

An AnalyzeMultiVars split object.

**Author(s)**

|-----------------|---|
| analyze_colvars | <i>Generate Rows Analyzing Different Variables Across Columns</i> |
|-----------------|---|

---

**Description**

Generate Rows Analyzing Different Variables Across Columns

**Usage**

```
analyze_colvars(
  lyt,
  afun,
  format = NULL,
  nested = TRUE,
  extra_args = list(),
  indent_mod = 0L,
  inclNAs = FALSE
)
```

**Arguments**

|            |  |
|------------|--|
| lyt        | layout object pre-data used for tabulation   |
| afun       | function or list. Function(s) to be used to calculate the values in each column. the list will be repped out as needed and matched by position with the columns during tabulation.   |
| format     | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| nested     | boolean. Should this layout instruction be applied within the existing layout structure <i>if possible</i> (TRUE, the default) or as a new top-level element ('FALSE). Ignored if it would nest a split underneath analyses, which is not allowed.               |
| extra_args | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function. |
| indent_mod | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.                 |
| inclNAs    | boolean. Should observations with NA in the var variable(s) be included when performing this analysis. Defaults to FALSE   |

**Value**

A PreDataTableLayouts object suitable for passing to further layouting functions, and to `build_table`.

tbl2 <- build_table(lyt2, ANL)
tbl2

```

---

append\_topleft

*Append a description to the 'top-left' materials for the layout*

---

## Description

This function *adds* newlines to the current set of "top-left materials".

## Usage

```
append_topleft(lyt, newlines)
```

## Arguments

|          |   |
|----------|---|
| lyt      | layout object pre-data used for tabulation              |
| newlines | character. The new line(s) to be added to the materials |

## Details

Adds newlines to the set of strings representing the 'top-left' materials declared in the layout (the content displayed to the left of the column labels when the resulting tables are printed).

Top-left material strings are stored and then displayed *exactly as is*, no structure or indenting is applied to them either when they are added or when they are displayed.

## Value

A PreDataTableLayouts object suitable for passing to further layouting functions, and to `build_table`.

**Note**

Currently, where in the construction of the layout this is called makes no difference, as it is independent of the actual splitting keywords. This may change in the future.

This function is experimental, its name and the details of its behavior are subject to change in future versions.

**See Also**

[top\\_left\(\)](#)

**Examples**

```
library(dplyr)

DM2 <- DM %>% mutate(RACE = factor(RACE), SEX = factor(SEX))

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_cols_by("SEX") %>%
  split_rows_by("RACE") %>%
  append_topleft("Ethnicity") %>%
  analyze("AGE") %>%
  append_topleft(" Age")

tbl <- build_table(lyt, DM2)
tbl
```

---

asvec

*convert to a vector*

---

**Description**

Convert an rtables framework object into a vector, if possible. This is unlikely to be useful in realistic scenarios.

**Usage**

```
## S4 method for signature 'VTableTree'
as.vector(x, mode = "any")
```

**Arguments**

x ANY. The object to be converted to a vector

mode character(1). Passed on to [as.vector](#)

**Value**

a vector of the chosen mode (or an error is raised if more than one row was present).

**Note**

This only works for a table with a single row or a row object.

---

|         |  |
|---------|--|
| as_html | <i>Convert an rtable object to a shiny.tag html object</i> |
|---------|--|

---

**Description**

The returned html object can be immediately used in shiny and rmarkdown.

**Usage**

```
as_html(  
  x,  
  width = NULL,  
  class_table = "table table-condensed table-hover",  
  class_tr = NULL,  
  class_td = NULL,  
  class_th = NULL,  
  link_label = NULL  
)
```

**Arguments**

|             |  |
|-------------|--|
| x           | rtable object  |
| width       | width  |
| class_table | class for table tag  |
| class_tr    | class for tr tag   |
| class_td    | class for td tag   |
| class_th    | class for th tag   |
| link_label  | link anchor label (not including tab: prefix) for the table. |

**Value**

A shiny.tag object representing x in HTML.

**Examples**

```
tbl <- rtable(  
  header = LETTERS[1:3],  
  format = "xx",  
  rrow("r1", 1,2,3),  
  rrow("r2", 4,3,2, indent = 1),  
  rrow("r3", indent = 2)  
)
```

```

as_html(tbl)

as_html(tbl, class_table = "table", class_tr = "row")

as_html(tbl, class_td = "aaa")

## Not run:
Viewer(tbl)

## End(Not run)

```

---

basic\_table

*Layout with 1 column and zero rows*

---

## Description

Every layout must start with a basic table.

## Usage

```

basic_table(
  title = "",
  subtitles = character(),
  main_footer = character(),
  prov_footer = character(),
  show_colcounts = FALSE,
  colcount_format = "(N=xx)",
  inset = 0L
)

```

## Arguments

|                 |   |
|-----------------|---|
| title           | character(1). Main title. Ignored for subtables.  |
| subtitles       | character. Subtitles. Ignored for subtables.  |
| main_footer     | character. Main global (non-referential) footer materials.  |
| prov_footer     | character. Provenance-related global footer materials. Generally should not be modified by hand.  |
| show_colcounts  | logical(1). Should column counts be displayed in the resulting table when this layout is applied to data  |
| colcount_format | character(1). Format for use when displaying the column counts. Must be 1d, or 2d where one component is a percent. See details.  |
| inset           | numeric(1). Number of spaces to inset the table header, table body, referential footnotes, and main_footer, as compared to alignment of title, subtitle, and provenance footer. Defaults to 0 (no inset). |

**Details**

`colcount_format` is ignored if `show_colcounts` is `FALSE` (the default). When `show_colcounts` is `TRUE`, and `colcount_format` is 2-dimensional with a percent component, the value component for the percent is always populated with 1 (ie 100%). 1d formats are used to render the counts exactly as they normally would be, while 2d formats which don't include a percent, and all 3d formats result in an error. Formats in the form of functions are not supported for colcount format. See [list\\_valid\\_format\\_labels](#) for the list of valid format labels to select from.

**Value**

A `PreDataTableLayouts` object suitable for passing to further layouting functions, and to `build_table`.

**Note**

Because percent components in `colcount_format` are *always* populated with the value 1, we can get arguably strange results, such as that individual arm columns and a combined "all patients" column all list "100%" as their percentage, even though the individual arm columns represent strict subsets of the all patients column.

**Examples**

```
lyt <- basic_table() %>%
  analyze("AGE", afun = mean)

tbl <- build_table(lyt, DM)
tbl

lyt2 <- basic_table(title = "Title of table",
  subtitles = c("a number", "of subtitles"),
  main_footer = "test footer",
  prov_footer = paste("test.R program, executed at",
    Sys.time())) %>%
  split_cols_by("ARM") %>%
  analyze("AGE", mean)

tbl2 <- build_table(lyt2, DM)
tbl2

lyt3 <- basic_table(show_colcounts = TRUE,
  colcount_format = "xx. (xx.%)") %>%
  split_cols_by("ARM")
```

**Description**

Retrieve and assign elements of a TableTree

**Usage**

```
## S4 replacement method for signature 'VTableTree,ANY,ANY,list'
x[i, j, ...] <- value
```

```
## S4 method for signature 'VTableTree,logical,logical'
x[i, j, ..., drop = FALSE]
```

**Arguments**

|       |   |
|-------|---|
| x     | TableTree   |
| i     | index   |
| j     | index   |
| ...   | Includes  |
|       | <i>keep_topleft</i> logical(1) ([ only) Should the top-left material for the table be retained after subsetting. Defaults to TRUE if all rows are included (i.e. subsetting was by column), and drops it otherwise.                         |
|       | <i>keep_titles</i> logical(1) Should title information be retained. Defaults to FALSE.  |
|       | <i>keep_footers</i> logical(1) Should non-referential footer information be retained. Defaults to keep_titles.  |
|       | <i>reindex_refs</i> logical(1). Should referential footnotes be re-indexed as if the resulting subset is the entire table. Defaults to TRUE.  |
| value | Replacement value (list, TableRow, or TableTree)  |
| drop  | logical(1). Should the value in the cell be returned if one cell is selected by the combination of i and j. It is not possible to return a vector of values. To do so please consider using <code>cell_values()</code> . Defaults to FALSE. |

**Details**

by default, subsetting drops the information about title, subtitle, main footer, provenance footer, and topleft. If only a column is selected and all rows are kept, the topleft information remains as default. Any referential footnote is kept whenever the subset table contains the referenced element.

**Value**

a TableTree (or ElementaryTable) object, unless a single cell was selected with drop=TRUE, in which case the (possibly multi-valued) fully stripped raw value of the selected cell.

**Note**

subsetting always preserve the original order, even if provided indexes do not preserve it. If sorting is needed, please consider using `sort_at_path()`. Also note that character indices are treated as paths, not vectors of names in both `[]` and `[]<-`.

**See Also**

Regarding sorting: `sort_at_path()` and how to understand path structure: `summarize_row_groups()`, and `summarize_col_groups()`.

**Examples**

```
lyt <- basic_table(title = "Title",
                  subtitles = c("Sub", "titles"),
                  prov_footer = "prov footer",
                  main_footer = "main footer") %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX") %>%
  analyze(c("AGE"))

tbl <- build_table(lyt, DM)
top_left(tbl) <- "Info"
tbl

# As default header, footer, and topleft information is lost
tbl[1, ]
tbl[1:2, 2]

# Also boolean filters can work
tbl[, c(FALSE, TRUE, FALSE)]

# If drop = TRUE, the content values are directly retrieved
tbl[2, 1]
tbl[2, 1, drop = TRUE]

# Drop works also if vectors are selected, but not matrices
tbl[, 1, drop = TRUE]
tbl[2, , drop = TRUE]
tbl[1, 1, drop = TRUE] # NULL because it is a label row
tbl[2, 1:2, drop = TRUE] # vectors can be returned only with cell_values()
tbl[1:2, 1:2, drop = TRUE] # no dropping because it is a matrix

# If all rows are selected, topleft is kept by default
tbl[, 2]
tbl[, 1]

# It is possible to deselect values
tbl[-2, ]
tbl[, -1]

# Values can be reassigned
tbl[2, 1] <- rcell(999)
tbl[2, ] <- list(rrow("FFF", 888, 666, 777))
tbl[6, ] <- list(-111, -222, -333)
tbl

# We can keep some information from the original table if we need
tbl[1, 2, keep_titles = TRUE]
```

```
tbl[1, 2, keep_footers = TRUE, keep_titles = FALSE]
tbl[1, 2, keep_footers = FALSE, keep_titles = TRUE]
tbl[1, 2, keep_footers = TRUE]
tbl[1, 2, keep_topleft = TRUE]

# Keeps the referential footnotes when subset contains them
fnotes_at_path(tbl, rowpath = c("SEX", "M", "AGE", "Mean")) <- "important"
tbl[4, 1]
tbl[2, 1] # None present

# We can reindex referential footnotes, so that the new table does not depend
# on the original one
fnotes_at_path(tbl, rowpath = c("SEX", "U", "AGE", "Mean")) <- "important"
tbl[, 1] # both present
tbl[5:6, 1] # {1} because it has been indexed again
tbl[5:6, 1, reindex_refs = FALSE] # {2} -> not reindexed

# Note that order can not be changed with subsetting
tbl[c(4, 3, 1), c(3, 1)] # It preserves order and wanted selection
```

---

build\_table

*Create a table from a layout and data*

---

## Description

Layouts are used to describe a table pre-data. `build_table` is used to create a table using a layout and a dataset.

## Usage

```
build_table(
  lyt,
  df,
  alt_counts_df = NULL,
  col_counts = NULL,
  col_total = if (is.null(alt_counts_df)) nrow(df) else nrow(alt_counts_df),
  topleft = NULL,
  hsep = default_hsep(),
  ...
)
```

## Arguments

|                            |  |
|----------------------------|--|
| <code>lyt</code>           | layout object pre-data used for tabulation   |
| <code>df</code>            | dataset (data.frame or tibble)   |
| <code>alt_counts_df</code> | dataset (data.frame or tibble). Alternative full data the rtables framework will use ( <i>only</i> ) when calculating column counts. |

|            |  |
|------------|--|
| col_counts | numeric (or NULL). Deprecated. If non-null, column counts which override those calculated automatically during tabulation. Must specify "counts" for <i>all</i> resulting columns if non-NULL. NA elements will be replaced with the automatically calculated counts.            |
| col_total  | integer(1). The total observations across all columns. Defaults to nrow(df).   |
| topleft    | character. Override values for the "top left" material to be displayed during printing.  |
| hsep       | character(1). Set of character(s) to be repeated as the separator between the header and body of the table when rendered as text. Defaults to a connected horizontal line (unicode 2014) in locals that use a UTF charset, and to - elsewhere (with a once per session warning). |
| ...        | currently ignored.   |

### Details

When `alt_counts_df` is specified, column counts are calculated by applying the exact column sub-setting expressions determined when applying column splitting to the main data (`df`) to `alt_counts_df` and counting the observations in each resulting subset.

In particular, this means that in the case of splitting based on cuts of the data, any dynamic cuts will have been calculated based on `df` and simply re-used for the count calculation.

### Value

A `TableTree` or `ElementaryTable` object representing the table created by performing the tabulations declared in `lyt` to the data `df`.

### Note

When overriding the column counts or totals care must be taken that, e.g., `length()` or `nrow()` are not called within tabulation functions, because those will NOT give the overridden counts. Writing/using tabulation functions which accept `.N_col` and `.N_total` or do not rely on column counts at all (even implicitly) is the only way to ensure overridden counts are fully respected.

### Author(s)

Gabriel Becker

### Examples

```
lyt <- basic_table() %>%
  split_cols_by("Species") %>%
  analyze("Sepal.Length", afun = function(x) {
    list(
      "mean (sd)" = rcell(c(mean(x), sd(x)), format = "xx.xx (xx.xx)"),
      "range" = diff(range(x))
    )
  })
```

```

lyt

tbl1 <- build_table(lyt, iris)
tbl1

# analyze multiple variables
lyt2 <- basic_table() %>%
  split_cols_by("Species") %>%
  analyze(c("Sepal.Length", "Petal.Width"), afun = function(x) {
    list(
      "mean (sd)" = rcell(c(mean(x), sd(x)), format = "xx.xx (xx.xx)"),
      "range" = diff(range(x))
    )
  })

tbl2 <- build_table(lyt2, iris)
tbl2

# an example more relevant for clinical trials with column counts
lyt3 <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM") %>%
  analyze("AGE", afun = function(x) {
    setNames(as.list(fivenum(x)), c("minimum", "lower-hinge", "median",
      "upper-hinge", "maximum"))
  })

tbl3 <- build_table(lyt3, DM)
tbl3

tbl4 <- build_table(lyt3, subset(DM, AGE > 40))
tbl4

# with column counts calculated based on different data
miniDM <- DM[sample(1:NROW(DM), 100),]
tbl5 <- build_table(lyt3, DM, alt_counts_df = miniDM)
tbl5

tbl6 <- build_table(lyt3, DM, col_counts = 1:3)
tbl6

cbind\_rtables

*cbind two rtables*

---

## Description

cbind two rtables

## Usage

```
cbind_rtables(x, ...)
```

**Arguments**

x                    A table or row object  
...                   1 or more further objects of the same class as x

**Value**

A formal table object.

**Examples**

```
x <- rtable(c("A", "B"), rrow("row 1", 1,2), rrow("row 2", 3, 4))
y <- rtable("C", rrow("row 1", 5), rrow("row 2", 6))
z <- rtable("D", rrow("row 1", 9), rrow("row 2", 10))

t1 <- cbind_rtables(x, y)
t1

t2 <- cbind_rtables(x, y, z)
t2

col_paths_summary(t1)
col_paths_summary(t2)
```

---

CellValue

*Cell Value constructor*

---

**Description**

Cell Value constructor

**Usage**

```
CellValue(
  val,
  format = NULL,
  colspan = 1L,
  label = NULL,
  indent_mod = NULL,
  footnotes = NULL,
  align = NULL,
  format_na_str = NULL
)
```

**Arguments**

|               |  |
|---------------|--|
| val           | ANY. value in the cell exactly as it should be passed to a formatter or returned when extracted  |
| format        | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| colspan       | integer(1). Column span value.   |
| label         | character(1). A label (not to be confused with the name) for the object/structure.   |
| indent_mod    | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior. |
| footnotes     | list or NULL. Referential footnote messages for the cell.  |
| align         | character(1) or NULL. Alignment the value should be rendered with. It defaults to "center" if NULL is used. See <a href="#">rtables_aligns</a> for currently supported alignments.   |
| format_na_str | character(1). String which should be displayed when formatted if this cell's value(s) are all NA.  |

**Value**

An object representing the value within a single cell within a populated table. The underlying structure of this object is an implementation detail and should not be relied upon beyond calling accessors for the class.

---

|             |  |
|-------------|--|
| cell_values | <i>Retrieve cell values by row and column path</i> |
|-------------|--|

---

**Description**

Retrieve cell values by row and column path

**Usage**

```
cell_values(tt, rowpath = NULL, colpath = NULL, omit_labrows = TRUE)
```

```
value_at(tt, rowpath = NULL, colpath = NULL)
```

```
## S4 method for signature 'VTableTree'
value_at(tt, rowpath = NULL, colpath = NULL)
```

**Arguments**

|              |  |
|--------------|--|
| tt           | TableTree (or related class). A TableTree object representing a populated table.   |
| rowpath      | character. Path in row-split space to the desired row(s). Can include "@content".  |
| colpath      | character. Path in column-split space to the desired column(s). Can include "*".   |
| omit_labrows | logical(1). Should label rows underneath rowpath be omitted (TRUE, the default), or return empty lists of cell "values" (FALSE). |

**Value**

for `cell_values`, a *list* (regardless of the type of value the cells hold). if `rowpath` defines a path to a single row, `cell_values` returns the list of cell values for that row, otherwise a list of such lists, one for each row captured underneath `rowpath`. This occurs after subsetting to `colpath` has occurred.

For `value_at` the "unwrapped" value of a single cell, or an error, if the combination of `rowpath` and `colpath` do not define the location of a single cell in `tt`.

**Note**

`cell_values` will return a single cell's value wrapped in a list. Use `value_at` to receive the "bare" cell value.

**Examples**

```
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_cols_by("SEX") %>%
  split_rows_by("RACE") %>%
  summarize_row_groups() %>%
  split_rows_by("STRATA1") %>%
  analyze("AGE")

library(dplyr) ## for mutate
tbl <- build_table(lyt, DM %>%
  mutate(SEX = droplevels(SEX), RACE = droplevels(RACE)))

row_paths_summary(tbl)
col_paths_summary(tbl)

cell_values(tbl, c("RACE", "ASIAN", "STRATA1", "B"),
  c("ARM", "A: Drug X", "SEX", "F"))

# it's also possible to access multiple values by being less specific
cell_values(tbl, c("RACE", "ASIAN", "STRATA1"),
  c("ARM", "A: Drug X", "SEX", "F"))
cell_values(tbl, c("RACE", "ASIAN"), c("ARM", "A: Drug X", "SEX", "M"))

## any arm, male columns from the ASIAN content (ie summary) row
cell_values(tbl, c("RACE", "ASIAN", "@content"),
  c("ARM", "B: Placebo", "SEX", "M"))
cell_values(tbl, c("RACE", "ASIAN", "@content"),
  c("ARM", "*", "SEX", "M"))

## all columns
cell_values(tbl, c("RACE", "ASIAN", "STRATA1", "B"))

## all columns for the Combination arm
cell_values(tbl, c("RACE", "ASIAN", "STRATA1", "B"),
  c("ARM", "C: Combination"))
```

```

cvlist <- cell_values(tbl, c("RACE", "ASIAN", "STRATA1", "B", "AGE", "Mean"),
  c("ARM", "B: Placebo", "SEX", "M"))
cvnolist <- value_at(tbl, c("RACE", "ASIAN", "STRATA1", "B", "AGE", "Mean"),
  c("ARM", "B: Placebo", "SEX", "M"))
stopifnot(identical(cvlist[[1]], cvnolist))

```

## S4 replacement method for signature 'VTableNodeInfo'
col_total(obj) <- value

```

### Arguments

|        |   |
|--------|---|
| obj    | ANY. The object for the accessor to access or modify  |
| object | The object to modify in-place   |
| value  | The new value   |
| df     | data.frame/NULL. Data to use if the column information is being generated from a Pre-Data layout object |
| rtpos  | TreePos. Root position.   |
| path   | character or NULL. col_counts getter and setter only. Path (in column structure).                       |

### Value

A LayoutColTree object.  
 Various column information, depending on the accessor used.

---

|                   |   |
|-------------------|---|
| clear_indent_mods | <i>Clear All Indent Mods from a Table</i> |
|-------------------|---|

---

### Description

Clear All Indent Mods from a Table

### Usage

```

clear_indent_mods(tt)

## S4 method for signature 'VTableTree'
clear_indent_mods(tt)

## S4 method for signature 'TableRow'
clear_indent_mods(tt)

```

**Arguments**

`tt` TableTree (or related class). A TableTree object representing a populated table.

**Value**

The same class as `tt`, with all indent mods set to zero.

**Examples**

```
lyt1 <- basic_table() %>%
  summarize_row_groups("STUDYID", label_fstr = "overall summary") %>%
  split_rows_by("AEBODSYS", child_labels = "visible") %>%
  summarize_row_groups("STUDYID", label = "subgroup summary") %>%
  analyze("AGE", indent_mod = -1L)

tbl1 <- build_table(lyt1, ex_adae)
tbl1
clear_indent_mods(tbl1)
```

---

|                |                                       |
|----------------|---------------------------------------|
| collect_leaves | <i>Collect leaves of a table tree</i> |
|----------------|---------------------------------------|

---

**Description**

Collect leaves of a table tree

**Usage**

```
collect_leaves(tt, incl.cont = TRUE, add.labrows = FALSE)
```

**Arguments**

`tt` TableTree (or related class). A TableTree object representing a populated table.

`incl.cont` logical. Include rows from content tables within the tree. Defaults to TRUE

`add.labrows` logical. Include label rows. Defaults to FALSE

**Value**

A list of TableRow objects for all rows in the table

---

|                 |                            |
|-----------------|----------------------------|
| compare_rtables | <i>Compare two rtables</i> |
|-----------------|----------------------------|

---

### Description

Prints a matrix where . means cell matches, X means cell does not match, + cell (row) is missing, and - cell (row) should not be there. If structure is set to TRUE, C indicates columnar structure mismatch, R indicates row-structure mismatch, and S indicates mismatch in both row and column structure.

### Usage

```
compare_rtables(
  object,
  expected,
  tol = 0.1,
  comp.attr = TRUE,
  structure = FALSE
)
```

### Arguments

|           |  |
|-----------|--|
| object    | rtable to test   |
| expected  | rtable expected  |
| tol       | numerical tolerance  |
| comp.attr | boolean. Compare format of cells. Other attributes are silently ignored.   |
| structure | boolean. Should structure (in the form of column and row paths to cells) be compared. Currently defaults to FALSE, but this is subject to change in future versions. |

### Value

a matrix of class "rtables\_diff" representing the differences between object and expected as described above.

### Note

In its current form compare\_rtables does not take structure into account, only row and cell position.

### Examples

```
t1 <- rtable(header = c("A", "B"), format = "xx", rrow("row 1", 1, 2))
t2 <- rtable(header = c("A", "B", "C"), format = "xx", rrow("row 1", 1, 2, 3))

compare_rtables(object = t1, expected = t2)
```

```

if(interactive()){
Viewer(t1, t2)
}

expected <- rtable(
  header = c("ARM A\nN=100", "ARM B\nN=200"),
  format = "xx",
  rrow("row 1", 10, 15),
  rrow(),
  rrow("section title"),
  rrow("row colspan", rcell(c(.345543, .4432423), colspan = 2, format = "(xx.xx, xx.xx)"))
)

expected

object <- rtable(
  header = c("ARM A\nN=100", "ARM B\nN=200"),
  format = "xx",
  rrow("row 1", 10, 15),
  rrow("section title"),
  rrow("row colspan", rcell(c(.345543, .4432423), colspan = 2, format = "(xx.xx, xx.xx)"))
)

compare_rtables(object, expected, comp.attr = FALSE)

object <- rtable(
  header = c("ARM A\nN=100", "ARM B\nN=200"),
  format = "xx",
  rrow("row 1", 10, 15),
  rrow(),
  rrow("section title")
)

compare_rtables(object, expected)

object <- rtable(
  header = c("ARM A\nN=100", "ARM B\nN=200"),
  format = "xx",
  rrow("row 1", 14, 15.03),
  rrow(),
  rrow("section title"),
  rrow("row colspan", rcell(c(.345543, .4432423), colspan = 2, format = "(xx.xx, xx.xx)"))
)

compare_rtables(object, expected)

object <- rtable(
  header = c("ARM A\nN=100", "ARM B\nN=200"),
  format = "xx",
  rrow("row 1", 10, 15),
  rrow(),
  rrow("section title"),

```

```

    rrow("row colspan", rcell(c(.345543, .4432423), colspan = 2, format = "(xx.x, xx.x)"))
)

compare_rtables(object, expected)

```

---

compat\_args

*Compatibility Arg Conventions*

---

## Description

Compatibility Arg Conventions

## Usage

```
compat_args(.lst, row.name, format, indent, label, inset)
```

## Arguments

|          |   |
|----------|---|
| .lst     | list. An already-collected list of arguments to be used instead of the elements of <code>...</code> . Arguments passed via <code>...</code> will be ignored if this is specified.                                       |
| row.name | if NULL then an empty string is used as row.name of the <code>rrow</code> .   |
| format   | character(1) or function. The format label (string) or formatter function to apply to the cell values passed via <code>...</code> . See <a href="#">list_valid_format_labels</a> for currently supported format labels. |
| indent   | deprecated.   |
| label    | character(1). A label (not to be confused with the name) for the object/structure.  |
| inset    | integer(1). The table inset for the row or table being constructed. See <a href="#">table_inset</a> .   |

## Value

NULL (this is an argument template dummy function)

## See Also

Other conventions: [constr\\_args\(\)](#), [gen\\_args\(\)](#), [lyt\\_args\(\)](#), [sf\\_args\(\)](#)

---

 constr\_args

*Constructor Arg Conventions*

---

**Description**

Constructor Arg Conventions

**Usage**

```

constr_args(
  kids,
  cont,
  lev,
  iscontent,
  cinfo,
  labelrow,
  vals,
  cspan,
  label_pos,
  cindent_mod,
  cvar,
  label,
  cextra_args,
  child_names,
  title,
  subtitles,
  main_footer,
  prov_footer,
  footnotes,
  page_title,
  page_prefix,
  section_div,
  trailing_sep,
  split_na_str,
  cna_str,
  inset,
  table_inset
)

```

**Arguments**

|           |  |
|-----------|--|
| kids      | list. List of direct children.   |
| cont      | ElementaryTable. Content table.  |
| lev       | integer. Nesting level (roughly, indentation level in practical terms).                              |
| iscontent | logical. Is the TableTree/ElementaryTable being constructed the content table for another TableTree. |

|              |   |
|--------------|---|
| cinfo        | InstantiatedColumnInfo (or NULL). Column structure for the object being created.  |
| labelrow     | LabelRow. The LabelRow object to assign to this Table. Constructed from label by default if not specified.  |
| vals         | list. cell values for the row   |
| cspan        | integer. Column span. 1 indicates no spanning.  |
| label_pos    | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting.  |
| cindent_mod  | numeric(1). The indent modifier for the content tables generated by this split.   |
| cvar         | character(1). The variable, if any, which the content function should accept. Defaults to NA.   |
| label        | character(1). A label (not to be confused with the name) for the object/structure.  |
| cextra_args  | list. Extra arguments to be passed to the content function when tabulating row group summaries.   |
| child_names  | character. Names to be given to the sub splits contained by a compound split (typically a AnalyzeMultiVars split object).   |
| title        | character(1). Main title. Ignored for subtables.  |
| subtitles    | character. Subtitles. Ignored for subtables.  |
| main_footer  | character. Main global (non-referential) footer materials.  |
| prov_footer  | character. Provenance-related global footer materials. Generally should not be modified by hand.  |
| footnotes    | list or NULL. Referential footnotes to be applied at current level  |
| page_title   | character. Page specific title(s).  |
| page_prefix  | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table   |
| section_div  | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.   |
| trailing_sep | character(1). String which will be used as a section divider after the printing of the last row contained in this (sub)-table, unless that row is also the last table row to be printed overall, or NA_character_ for none (the default). When generated via layouting, this would correspond to the section_div of the split under which this table represents a single facet. |
| split_na_str | character. NA string vector for use with split_format.  |
| cna_str      | character. NA string for use with cformat for content table.  |
| inset        | numeric(1). Number of spaces to inset the table header, table body, referential footnotes, and main_footer, as compared to alignment of title, subtitle, and provenance footer. Defaults to 0 (no inset).   |
| table_inset  | numeric(1). Number of spaces to inset the table header, table body, referential footnotes, and main_footer, as compared to alignment of title, subtitle, and provenance footer. Defaults to 0 (no inset).   |

**Value**

NULL (this is an argument template dummy function)

**See Also**

Other conventions: [compat\\_args\(\)](#), [gen\\_args\(\)](#), [lyt\\_args\(\)](#), [sf\\_args\(\)](#)

---

|               |   |
|---------------|---|
| content_table | <i>Retrieve or set Content Table from a TableTree</i> |
|---------------|---|

---

**Description**

Returns the content table of obj if it is a TableTree object, or NULL otherwise

**Usage**

```
content_table(obj)
```

```
content_table(obj) <- value
```

**Arguments**

|       |   |
|-------|---|
| obj   | TableTree. The TableTree                        |
| value | ElementaryTable. The new content table for obj. |

**Value**

the ElementaryTable containing the (top level) *content rows* of obj ( or NULL if obj is not a formal table object).

---

|                |   |
|----------------|---|
| cont_n_allcols | <i>Score functions for sorting TableTrees</i> |
|----------------|---|

---

**Description**

Score functions for sorting TableTrees

**Usage**

```
cont_n_allcols(tt)
```

```
cont_n_onecol(j)
```

**Arguments**

`tt` TableTree (or related class). A TableTree object representing a populated table.  
`j` numeric(1). Number of column used for scoring.

**Value**

A single numeric value indicating score according to the relevant metric for `tt`, to be used when sorting.

**See Also**

For examples and details please read main documentation [sort\\_at\\_path\(\)](#) and relevant vignette ([\(\(Sorting and Pruning\)\)](#))

---

|              |  |
|--------------|--|
| counts_wpcts | <i>Analysis function to count levels of a factor with percentage of the column total</i> |
|--------------|--|

---

**Description**

Analysis function to count levels of a factor with percentage of the column total

**Usage**

```
counts_wpcts(x, .N_col)
```

**Arguments**

`x` factor. Vector of data, provided by rtables pagination machinery  
`.N_col` integer(1). Total count for the column, provided by rtables pagination machinery

**Value**

A RowsVerticalSection object with counts (and percents) for each level of the factor

**Examples**

```
counts_wpcts(DM$SEX, 400)
```

## Description

Split functions provide the work-horse for `rtables`'s generalized partitioning. These functions accept a (sub)set of incoming data, a split object, and return 'splits' of that data.

## Custom Splitting Function Details

User-defined custom split functions can perform any type of computation on the incoming data provided that they meet the contract for generating 'splits' of the incoming data 'based on' the split object.

Split functions are functions that accept:

**df** `data.frame` of incoming data to be split

**spl** a Split object. this is largely an internal detail custom functions will not need to worry about, but `obj_name(spl)`, for example, will give the name of the split as it will appear in paths in the resulting table

**vals** Any pre-calculated values. If given non-null values, the values returned should match these. Should be NULL in most cases and can likely be ignored

**labels** Any pre-calculated value labels. Same as above for values

**trim** If TRUE, resulting splits that are empty should be removed

**(Optional) .spl\_context** a `data.frame` describing previously performed splits which collectively arrived at `df`

The function must then output a named `list` with the following elements:

**values** The vector of all values corresponding to the splits of `df`

**datasplit** a list of `data.frames` representing the groupings of the actual observations from `df`.

**labels** a character vector giving a string label for each value listed in the `values` element above

**(Optional) extras** If present, extra arguments are to be passed to summary and analysis functions whenever they are executed on the corresponding element of `datasplit` or a subset thereof

One way to generate custom splitting functions is to wrap existing split functions and modify either the incoming data before they are called or their outputs.

## See Also

[make\\_split\\_fun\(\)](#) for the API for creating custom split functions, and [split\\_funs](#) for a variety of pre-defined split functions.

## Examples

```

# Example of a picky split function. The number of values in the column variable
# var decrees if we are going to print also the column with all observation
# or not.

picky_splitter <- function(var) {
  # Main layout function
  function(df, spl, vals, labels, trim) {
    orig_vals <- vals

    # Check for number of levels if all are selected
    if (is.null(vals)) {
      vec <- df[[var]]
      vals <- unique(vec)
    }

    # Do a split with or without All obs
    if (length(vals) == 1) {
      do_base_split(spl = spl, df = df, vals = vals, labels = labels, trim = trim)
    } else {
      fnc_tmp <- add_overall_level("Overall", label = "All Obs", first = FALSE)
      fnc_tmp(df = df, spl = spl, vals = orig_vals, trim = trim)
    }
  }
}

# Data sub-set
d1 <- subset(ex_adsl, ARM == "A: Drug X" | (ARM == "B: Placebo" & SEX == "F"))
d1 <- subset(d1, SEX %in% c("M", "F"))
d1$SEX <- factor(d1$SEX)

# This table uses the number of values in the SEX column to add the overall col or not
lyt <- basic_table() %>%
  split_cols_by("ARM", split_fun = drop_split_levels) %>%
  split_cols_by("SEX", split_fun = picky_splitter("SEX")) %>%
  analyze("AGE", show_labels = "visible")
tbl <- build_table(lyt, d1)
tbl

```

---

df\_to\_tt

*Create ElementaryTable from data.frame*

---

## Description

Create ElementaryTable from data.frame

## Usage

```
df_to_tt(df)
```

**Arguments**

df                    data.frame.

**Value**

an ElementaryTable object with unnested columns corresponding to names(df) and row labels corresponding to row.names(df)

**Examples**

```
df_to_tt(mtcars)
```

---

|               |  |
|---------------|--|
| do_base_split | <i>Apply Basic Split (For Use In Custom Split Functions)</i> |
|---------------|--|

---

**Description**

This function is intended for use inside custom split functions. It applies the current split *as if it had no custom splitting function* so that those default splits can be further manipulated.

**Usage**

```
do_base_split(spl, df, vals = NULL, labels = NULL, trim = FALSE)
```

**Arguments**

spl                    A Split object defining a partitioning or analysis/tabulation of the data.

df                    dataset (data.frame or tibble)

vals                  ANY. Already calculated/known values of the split. Generally should be left as NULL.

labels                character. Labels associated with vals. Should be NULL when vals is, which should almost always be the case.

trim                  logical(1). Should groups corresponding to empty data subsets be removed. Defaults to FALSE.

**Value**

the result of the split being applied as if it had no custom split function, see [custom\\_split\\_funs](#)

**Examples**

```

uneven_splfun <- function(df, spl, vals = NULL, labels = NULL, trim = FALSE) {
  ret <- do_base_split(spl, df, vals, labels, trim)
  if(NROW(df) == 0)
    ret <- lapply(ret, function(x) x[1])
  ret
}

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_cols_by_multivar(c("USUBJID", "AESEQ", "BMRKR1"),
    varlabels = c("N", "E", "BMR1"),
    split_fun = uneven_splfun) %>%
  analyze_colvars(list(USUBJID = function(x, ...) length(unique(x)),
    AESEQ = max,
    BMRKR1 = mean))

tbl <- build_table(lyt, subset(ex_adae, as.numeric(ARM) <= 2))
tbl

```

---

drop\_facet\_levels

*Preprocessing Functions for use in make\_split\_fun*

---

**Description**

This function is intended for use as a preprocessing component in `make_split_fun`, and should not be called directly by end users.

**Usage**

```
drop_facet_levels(df, spl, ...)
```

**Arguments**

`df` data.frame. The incoming data corresponding with the parent facet  
`spl` Split.  
`...` dots. This is used internally to pass parameters.

**See Also**

`make_split_fun`

Other `make_custom_split`: [add\\_combo\\_facet\(\)](#), [make\\_split\\_fun\(\)](#), [make\\_split\\_result\(\)](#), [trim\\_levels\\_in\\_facets\(\)](#)

 ElementaryTable-class *TableTree classes*

---

**Description**

TableTree classes

Table Constructors and Classes

**Usage**

```
ElementaryTable(
  kids = list(),
  name = "",
  lev = 1L,
  label = "",
  labelrow = LabelRow(lev = lev, label = label, vis = !isTRUE(iscontent) && !is.na(label)
    && nzchar(label)),
  rspan = data.frame(),
  cinfo = NULL,
  iscontent = NA,
  var = NA_character_,
  format = NULL,
  na_str = NA_character_,
  indent_mod = 0L,
  title = "",
  subtitles = character(),
  main_footer = character(),
  prov_footer = character(),
  hsep = default_hsep(),
  trailing_sep = NA_character_,
  inset = 0L
)
```

```
TableTree(
  kids = list(),
  name = if (!is.na(var)) var else "",
  cont = EmptyElTable,
  lev = 1L,
  label = name,
  labelrow = LabelRow(lev = lev, label = label, vis = nrow(cont) == 0 && !is.na(label) &&
    nzchar(label)),
  rspan = data.frame(),
  iscontent = NA,
  var = NA_character_,
  cinfo = NULL,
  format = NULL,
```

```

na_str = NA_character_,
indent_mod = 0L,
title = "",
subtitles = character(),
main_footer = character(),
prov_footer = character(),
page_title = NA_character_,
hsep = default_hsep(),
trailing_sep = NA_character_,
inset = 0L
)

```

### Arguments

|             |  |
|-------------|--|
| kids        | list. List of direct children.   |
| name        | character(1). Name of the split/table/row being created. Defaults to same as the corresponding label, but is not required to be.   |
| lev         | integer. Nesting level (roughly, indentation level in practical terms).  |
| label       | character(1). A label (not to be confused with the name) for the object/structure.   |
| labelrow    | LabelRow. The LabelRow object to assign to this Table. Constructed from label by default if not specified.   |
| rspans      | data.frame. Currently stored but otherwise ignored.  |
| cinfo       | InstantiatedColumnInfo (or NULL). Column structure for the object being created.   |
| iscontent   | logical. Is the TableTree/ElementaryTable being constructed the content table for another TableTree.   |
| var         | string, variable name  |
| format      | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| na_str      | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".  |
| indent_mod  | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.                                 |
| title       | character(1). Main title. Ignored for subtables.   |
| subtitles   | character. Subtitles. Ignored for subtables.   |
| main_footer | character. Main global (non-referential) footer materials.   |
| prov_footer | character. Provenance-related global footer materials. Generally should not be modified by hand.   |
| hsep        | character(1). Set of character(s) to be repeated as the separator between the header and body of the table when rendered as text. Defaults to a connected horizontal line (unicode 2014) in locals that use a UTF charset, and to - elsewhere (with a once per session warning). |

|              |   |
|--------------|---|
| trailing_sep | character(1). String which will be used as a section divider after the printing of the last row contained in this (sub)-table, unless that row is also the last table row to be printed overall, or NA_character_ for none (the default). When generated via layouting, this would correspond to the section_div of the split under which this table represents a single facet. |
| inset        | numeric(1). Number of spaces to inset the table header, table body, referential footnotes, and main_footer, as compared to alignment of title, subtitle, and provenance footer. Defaults to 0 (no inset).   |
| cont         | ElementaryTable. Content table.   |
| page_title   | character. Page specific title(s).  |

**Value**

A formal object representing a populated table.

**Author(s)**

Gabriel Becker

---

|              |   |
|--------------|---|
| EmptyColInfo | <i>Empty table, column, split objects</i> |

|---------------|----------------------|
| export_as_pdf | <i>Export as PDF</i> |
|---------------|----------------------|

---

**Description**

The PDF output is based on the ASCII output created with toString

**Usage**

```
export_as_pdf(
  tt,
  file,
  page_type = "letter",
  landscape = FALSE,
  pg_width = page_dim(page_type)[if (landscape) 2 else 1],
  pg_height = page_dim(page_type)[if (landscape) 1 else 2],
  width = NULL,
  height = NULL,
  margins = c(4, 4, 4, 4),
```

```

font_family = "Courier",
font_size = 8,
font_size = font_size,
paginate = TRUE,
lpp = NULL,
cpp = NULL,
hsep = "-",
indent_size = 2,
tf_wrap = TRUE,
max_width = NULL,
colwidths = propose_column_widths(matrix_form(tt, TRUE)),
...
)

```

### Arguments

|                          |   |
|--------------------------|---|
| <code>tt</code>          | TableTree (or related class). A TableTree object representing a populated table.  |
| <code>file</code>        | file to write, must have .pdf extension   |
| <code>page_type</code>   | character(1). Name of a page type. See <code>page_types</code> . Ignored when <code>pg_width</code> and <code>pg_height</code> are set directly.  |
| <code>landscape</code>   | logical(1). Should the dimensions of <code>page_type</code> be inverted for landscape? Defaults to FALSE, ignored when <code>pg_width</code> and <code>pg_height</code> are set directly.       |
| <code>pg_width</code>    | numeric(1). Page width in inches.   |
| <code>pg_height</code>   | numeric(1). Page height in inches.  |
| <code>width</code>       | Deprecated, please use <code>pg_width</code> or specify <code>page_type</code> . The width of the graphics region in inches   |
| <code>height</code>      | Deprecated, please use <code>pg_height</code> or specify <code>page_type</code> . The height of the graphics region in inches   |
| <code>margins</code>     | numeric(4). The number of lines/characters of margin on the bottom, left, top, and right sides of the page.   |
| <code>font_family</code> | character(1). Name of a font family. An error will be thrown if the family named is not monospaced. Defaults to Courier.  |
| <code>font_size</code>   | Deprecated, please use <code>font_size</code> . the size of text (in points)  |
| <code>font_size</code>   | numeric(1). Font size, defaults to 12.  |
| <code>paginate</code>    | logical(1). Whether pagination should be performed, defaults to TRUE if page size is specified (including the default).   |
| <code>lpp</code>         | numeric(1) or NULL. Lines per page. if NA (the default, this is calculated automatically based on the specified page size). NULL indicates no vertical pagination should occur.                 |
| <code>cpp</code>         | numeric(1) or NULL. Width in characters per page. if NA (the default, this is calculated automatically based on the specified page size). NULL indicates no horizontal pagination should occur. |
| <code>hsep</code>        | character(1). Characters to repeat to create header/body separator line.  |

|             |  |
|-------------|--|
| indent_size | numeric(1). Indent size in characters. Ignored when x is already a MatrixPrint-Form object in favor of information there.  |
| tf_wrap     | logical(1). Should the texts for title, subtitle, and footnotes be wrapped?  |
| max_width   | integer(1), character(1) or NULL. Width that title and footer (including footnotes) materials should be word-wrapped to. If NULL, it is set to the current print width of the session ( <code>getOption("width")</code> ). If set to "auto", the width of the table (plus any table inset) is used. Ignored completely if <code>tf_wrap</code> is FALSE. |
| colwidths   | numeric vector. Column widths (in characters) for use with vertical pagination.  |
| ...         | arguments passed on to <code>paginate_table</code>   |

### Details

By default, pagination is performed, with default `cpp` and `lpp` defined by specified page dimensions and margins. User-specified `lpp` and `cpp` values override this, and should be used with caution.

Title and footer materials are also word-wrapped by default (unlike when printed to the terminal), with `cpp`, as defined above, as the default `max_width`.

export_as_pdf(tbl, file = tf, lpp = 8)

## End(Not run)
```

---

export\_as\_tsv

*Create Enriched flat value table with paths*

---

### Description

This function creates a flat tabular file of cell values and corresponding paths via [path\\_enriched\\_df](#). I then writes that data.frame out as a tsv file.

**Usage**

```

export_as_tsv(
  tt,
  file = NULL,
  path_fun = collapse_path,
  value_fun = collapse_values
)

import_from_tsv(file)

```

**Arguments**

|           |  |
|-----------|--|
| tt        | TableTree (or related class). A TableTree object representing a populated table.   |
| file      | character(1). The path of the file to written to or read from.   |
| path_fun  | function. Function to transform paths into single-string row/column names.   |
| value_fun | function. Function to transform cell values into cells of the data.frame. Defaults to collapse_values which creates strings where multi-valued cells are collapsed together, separated by  . |

**Details**

By default (ie when value\_func is not specified, List columns where at least one value has length > 1 are collapsed to character vectors by collapsing the list element with "|".

**Value**

NULL silently for export\_as\_tsv, a data.frame with re-constituted list values for export\_as\_tsv.

**Note**

There is currently no round-trip capability for this type of export. You can read values exported this way back in via import\_from\_tsv but you will receive only the data.frame version back, NOT a TableTree.

---

format\_rcell

*Format rcell*

---

**Description**

This is a wrapper around `formatters::format_value` for use with CellValue objects

**Usage**

```
format_rcell(
  x,
  format,
  output = c("ascii", "html"),
  na_str = obj_na_str(x) %||% "NA",
  pr_row_format = NULL,
  pr_row_na_str = NULL,
  shell = FALSE
)
```

**Arguments**

|               |  |
|---------------|--|
| x             | an object of class <code>CellValue</code> , or a raw value.  |
| format        | character(1) or function. The format label (string) or formatter function to apply to x.                             |
| output        | character(1). Output type.   |
| na_str        | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".                      |
| pr_row_format | list of default format coming from the general row.  |
| pr_row_na_str | list of default "NA" string coming from the general row.   |
| shell         | logical(1). Should the formats themselves be returned instead of the values with formats applied. Defaults to FALSE. |

**Value**

formatted text representing the cell

**Examples**

```
c11 <- CellValue(pi, format = "xx.xxx")
format_rcell(c11)

# Cell values precedes the row values
c11 <- CellValue(pi, format = "xx.xxx")
format_rcell(c11, pr_row_format = "xx.x")

# Similarly for NA values
c11 <- CellValue(NA, format = "xx.xxx", format_na_str = "This is THE NA")
format_rcell(c11, pr_row_na_str = "This is NA")
```

gen\_args

*General Argument Conventions***Description**

General Argument Conventions

**Usage**

```
gen_args(
  df,
  alt_counts_df,
  spl,
  pos,
  tt,
  tr,
  verbose,
  colwidths,
  obj,
  x,
  value,
  object,
  path,
  label,
  label_pos,
  cvar,
  topleft,
  page_prefix,
  hsep,
  indent_size,
  section_div,
  na_str,
  inset,
  table_inset,
  ...
)
```

**Arguments**

|               |  |
|---------------|--|
| df            | dataset (data.frame or tibble)   |
| alt_counts_df | dataset (data.frame or tibble). Alternative full data the rtables framework will use ( <i>only</i> ) when calculating column counts. |
| spl           | A Split object defining a partitioning or analysis/tabulation of the data.   |
| pos           | numeric. Which top-level set of nested splits should the new layout feature be added to. Defaults to the current                     |
| tt            | TableTree (or related class). A TableTree object representing a populated table.   |

|             |  |
|-------------|--|
| tr          | TableRow (or related class). A TableRow object representing a single row within a populated table.   |
| verbose     | logical(1). Should extra debugging messages be shown. Defaults to FALSE.   |
| colwidths   | numeric vector. Column widths for use with vertical pagination.  |
| obj         | ANY. The object for the accessor to access or modify   |
| x           | An object  |
| value       | The new value  |
| object      | The object to modify in-place  |
| path        | character. A vector path for a position within the structure of a tabletree. Each element represents a subsequent choice amongst the children of the previous choice.  |
| label       | character(1). A label (not to be confused with the name) for the object/structure.   |
| label_pos   | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| cvar        | character(1). The variable, if any, which the content function should accept. Defaults to NA.  |
| topleft     | character. Override values for the "top left" material to be displayed during printing.  |
| page_prefix | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table  |
| hsep        | character(1). Set of character(s) to be repeated as the separator between the header and body of the table when rendered as text. Defaults to a connected horizontal line (unicode 2014) in locals that use a UTF charset, and to - elsewhere (with a once per session warning).   |
| indent_size | numeric(1). Number of spaces to use per indent level. Defaults to 2  |
| section_div | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |
| na_str      | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".  |
| inset       | numeric(1). Number of spaces to inset the table header, table body, referential footnotes, and main_footer, as compared to alignment of title, subtitle, and provenance footer. Defaults to 0 (no inset).  |
| table_inset | numeric(1). Number of spaces to inset the table header, table body, referential footnotes, and main_footer, as compared to alignment of title, subtitle, and provenance footer. Defaults to 0 (no inset).  |
| ...         | Passed on to methods or tabulation functions.  |

**Value**

NULL (this is an argument template dummy function)

**Description**

get formatted cells

**Usage**

```
get_formatted_cells(obj, shell = FALSE)

## S4 method for signature 'TableTree'
get_formatted_cells(obj, shell = FALSE)

## S4 method for signature 'ElementaryTable'
get_formatted_cells(obj, shell = FALSE)

## S4 method for signature 'TableRow'
get_formatted_cells(obj, shell = FALSE)

## S4 method for signature 'LabelRow'
get_formatted_cells(obj, shell = FALSE)

get_cell_aligns(obj)

## S4 method for signature 'TableTree'
get_cell_aligns(obj)

## S4 method for signature 'ElementaryTable'
get_cell_aligns(obj)

## S4 method for signature 'TableRow'
get_cell_aligns(obj)

## S4 method for signature 'LabelRow'
get_cell_aligns(obj)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>obj</code>   | ANY. The object for the accessor to access or modify   |
| <code>shell</code> | logical(1). Should the formats themselves be returned instead of the values with formats applied. Defaults to FALSE. |

**Value**

the formatted print-strings for all (body) cells in obj.

**Examples**

```
library(dplyr)

iris2 <- iris %>%
  group_by(Species) %>%
  mutate(group = as.factor(rep_len(c("a", "b"), length.out = n()))) %>%
  ungroup()

tbl <- basic_table() %>%
  split_cols_by("Species") %>%
  split_cols_by("group") %>%
  analyze(c("Sepal.Length", "Petal.Width"), afun = list_wrap_x(summary), format = "xx.xx") %>%
  build_table(iris2)

get_formatted_cells(tbl)
```

---

 head

*Head and tail methods*

---

**Description**

Head and tail methods

**Usage**

```
head(x, ...)

## S4 method for signature 'VTableTree'
head(
  x,
  n = 6,
  ...,
  keep_topleft = TRUE,
  keep_titles = TRUE,
  keep_footers = keep_titles,
  reindex_refs = FALSE
)

tail(x, ...)

## S4 method for signature 'VTableTree'
tail(
  x,
```

```

n = 6,
...,
keep_topleft = TRUE,
keep_titles = TRUE,
keep_footers = keep_titles,
reindex_refs = FALSE
)

```

### Arguments

|              |   |
|--------------|---|
| x            | an object   |
| ...          | arguments to be passed to or from other methods.  |
| n            | an integer vector of length up to <code>dim(x)</code> (or 1, for non-dimensioned objects). Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of <code>n[i]</code> includes the first/last <code>n[i]</code> indices in that dimension, while a negative value excludes the last/first <code>abs(n[i])</code> , including all remaining indices. NA or non-specified values (when <code>length(n) &lt; length(dim(x))</code> ) select all indices in that dimension. Must contain at least one non-missing value. |
| keep_topleft | logical(1). If TRUE (the default), top_left material for the table will be carried over to the subset.  |
| keep_titles  | logical(1). If TRUE (the default), all title material for the table will be carried over to the subset.   |
| keep_footers | logical(1). If TRUE, all footer material for the table will be carried over to the subset. It defaults to <code>keep_titles</code> .  |
| reindex_refs | logical(1). Defaults to FALSE. If TRUE, referential footnotes will be reindexed for the subset.   |

---

|                |   |
|----------------|---|
| horizontal_sep | <i>Access or recursively set header-body separator for tables</i> |
|----------------|---|

---

### Description

Access or recursively set header-body separator for tables

### Usage

```

horizontal_sep(obj)

## S4 method for signature 'VTableTree'
horizontal_sep(obj)

horizontal_sep(obj) <- value

## S4 replacement method for signature 'VTableTree'

```

```
horizontal_sep(obj) <- value

## S4 replacement method for signature 'TableRow'
horizontal_sep(obj) <- value
```

### Arguments

**obj** ANY. The object for the accessor to access or modify  
**value** character(1). String to use as new header/body separator.

### Value

for `horizontal_sep` the string acting as the header separator. for `horizontal_sep<-`, the `obj`, with the new header separator applied recursively to it and all its subtables.

---

|        |  |
|--------|--|
| indent | <i>Change indentation of all rows in an rtable</i> |
|--------|--|

---

### Description

Change indentation of all rows in an rtable

### Usage

```
indent(x, by = 1)
```

### Arguments

**x** [rtable](#) object  
**by** integer to increase indentation of rows. Can be negative. If final indentation is smaller than 0 then the indentation is set to 0.

### Value

x with its indent modifier incremented by by.

### Examples

```
is_setosa <- iris$Species == "setosa"
m_tbl <- rtable(
  header = rheader(
    rrow(row.name = NULL, rcell("Sepal.Length", colspan = 2), rcell("Petal.Length", colspan=2)),
    rrow(NULL, "mean", "median", "mean", "median")
  ),
  rrow(
    row.name = "All Species",
    mean(iris$Sepal.Length), median(iris$Sepal.Length),
    mean(iris$Petal.Length), median(iris$Petal.Length),
```

```

    format = "xx.xx"
  ),
  rrow(
    row.name = "Setosa",
    mean(iris$Sepal.Length[is_setosa]), median(iris$Sepal.Length[is_setosa]),
    mean(iris$Petal.Length[is_setosa]), median(iris$Petal.Length[is_setosa]),
    format = "xx.xx"
  )
)
indent(m_tbl)
indent(m_tbl, 2)

```

---

 indent\_string

*Indent Strings*

---

## Description

Used in rtables to indent row names for the ASCII output.

## Usage

```
indent_string(x, indent = 0, incr = 2, including_newline = TRUE)
```

## Arguments

|                                |  |
|--------------------------------|--|
| <code>x</code>                 | a character vector   |
| <code>indent</code>            | a vector of length <code>length(x)</code> with non-negative integers |
| <code>incr</code>              | non-negative integer: number of spaces per indent level              |
| <code>including_newline</code> | boolean: should newlines also be indented                            |

## Value

`x` indented by left-padding with `codeindent*incr` white-spaces.

## Examples

```

indent_string("a", 0)
indent_string("a", 1)
indent_string(letters[1:3], 0:2)
indent_string(paste0(letters[1:3], "\n", LETTERS[1:3]), 0:2)

```

---

insert\_row\_at\_path      *Insert Row at Path*

---

### Description

Insert a row into an existing table directly before or directly after an existing data (i.e., non-content and non-label) row, specified by its path.

### Usage

```
insert_row_at_path(tt, path, value, after = FALSE)
```

```
## S4 method for signature 'VTableTree,DataRow'
insert_row_at_path(tt, path, value, after = FALSE)
```

```
## S4 method for signature 'VTableTree,ANY'
insert_row_at_path(tt, path, value)
```

### Arguments

|       |   |
|-------|---|
| tt    | TableTree (or related class). A TableTree object representing a populated table.  |
| path  | character. A vector path for a position within the structure of a tabletree. Each element represents a subsequent choice amongst the children of the previous choice. |
| value | The new value   |
| after | logical(1). Should value be added as a row directly before (FALSE, the default) or after (TRUE) the row specified by path.  |

### See Also

[DataRow\(\)](#) [rrow\(\)](#)

### Examples

```
lyt <- basic_table() %>%
  split_rows_by("COUNTRY", split_fun = keep_split_levels(c("CHN", "USA"))) %>%
  analyze("AGE")

tbl1 <- build_table(lyt, DM)

tbl2 <- insert_row_at_path(tbl1, c("COUNTRY", "CHN", "AGE", "Mean"),
  rrow("new row", 555))
tbl2

tbl3 <- insert_row_at_path(tbl2, c("COUNTRY", "CHN", "AGE", "Mean"),
  rrow("new row redux", 888),
  after = TRUE)
tbl3
```

---

|             |  |
|-------------|--|
| insert_rrow | <i>[DEPRECATED] insert rrows at (before) a specific location</i> |
|-------------|--|

---

### Description

This function is deprecated and will be removed in a future release of rtables. Please use [insert\\_row\\_at\\_path](#) or [label\\_at\\_path](#) instead.

### Usage

```
insert_rrow(tbl, rrow, at = 1, ascentent = FALSE)
```

### Arguments

|           |   |
|-----------|---|
| tbl       | rtable  |
| rrow      | rrow to append to rtable  |
| at        | position into which to put the rrow, defaults to beginning (ie 1) |
| ascentent | logical. Currently ignored.                                       |

### Value

A TableTree of the same specific class as tbl

### Note

Label rows (ie a row with no data values, only a row.name) can only be inserted at positions which do not already contain a label row when there is a non-trivial nested row structure in tbl

### Examples

```
o <- options(warn = 0)
lyt <- basic_table() %>%
  split_cols_by("Species") %>%
  analyze("Sepal.Length")

tbl <- build_table(lyt, iris)

insert_rrow(tbl, rrow("Hello World"))
insert_rrow(tbl, rrow("Hello World"), at = 2)

lyt2 <- basic_table() %>%
  split_cols_by("Species") %>%
  split_rows_by("Species") %>%
  analyze("Sepal.Length")

tbl2 <- build_table(lyt2, iris)

insert_rrow(tbl2, rrow("Hello World"))
```

```

insert_rrow(tbl2, rrow("Hello World"), at = 2)
insert_rrow(tbl2, rrow("Hello World"), at = 4)

insert_rrow(tbl2, rrow("new row", 5, 6, 7))

insert_rrow(tbl2, rrow("new row", 5, 6, 7), at = 3)

options(o)

```

---

InstantiatedColumnInfo-class  
*InstantiatedColumnInfo*

---

## Description

InstantiatedColumnInfo

## Usage

```

InstantiatedColumnInfo(
  treelyt = LayoutColTree(),
  csubs = list(expression(TRUE)),
  extras = list(list()),
  cnts = NA_integer_,
  total_cnt = NA_integer_,
  dispcounts = FALSE,
  countformat = "(N=xx)",
  count_na_str = "",
  topleft = character()
)

```

## Arguments

|              |   |
|--------------|---|
| treelyt      | LayoutColTree.  |
| csubs        | list. List of subsetting expressions  |
| extras       | list. Extra arguments associated with the columns   |
| cnts         | integer. Counts.  |
| total_cnt    | integer(1). Total observations represented across all columns.                                  |
| dispcounts   | logical(1). Should the counts be displayed as header info when the associated table is printed. |
| countformat  | character(1). Format for the counts if they are displayed                                       |
| count_na_str | character. NA string to be used when formatting counts. Defaults to "".                         |
| topleft      | character. Override values for the "top left" material to be displayed during printing.         |

**Value**

an InstantiateColumnInfo object.

---

|         |  |
|---------|--|
| in_rows | <i>Create multiple rows in analysis or summary functions</i> |
|---------|--|

---

**Description**

define the cells that get placed into multiple rows in a fun

**Usage**

```
in_rows(
  ...,
  .list = NULL,
  .names = NULL,
  .labels = NULL,
  .formats = NULL,
  .indent_mods = NULL,
  .cell_footnotes = list(NULL),
  .row_footnotes = list(NULL),
  .aligns = NULL,
  .format_na_strs = NULL
)
```

**Arguments**

|                 |  |
|-----------------|--|
| ...             | single row defining expressions  |
| .list           | list. list cell content, usually rcells, the .list is concatenated to ...  |
| .names          | character or NULL. Names of the returned list/structure.   |
| .labels         | character or NULL. labels for the defined rows   |
| .formats        | character or NULL. Formats for the values  |
| .indent_mods    | integer or NULL. Indent modifications for the defined rows.  |
| .cell_footnotes | list. Referential footnote messages to be associated by name with <i>cells</i>   |
| .row_footnotes  | list. Referential footnotes messages to be associated by name with <i>rows</i>   |
| .aligns         | character or NULL. Alignments for the cells. Standard for NULL is "center". See <a href="#">rtables_aligns</a> for currently supported alignments. |
| .format_na_strs | character or NULL. NA strings for the cells  |

**Value**

an RowsVerticalSection object (or NULL). The details of this object should be considered an internal implementation detail.

**See Also**[analyze\(\)](#)**Examples**

```

in_rows(1, 2, 3, .names = c("a", "b", "c"))
in_rows(1, 2, 3, .labels = c("a", "b", "c"))
in_rows(1, 2, 3, .names = c("a", "b", "c"), .labels = c("AAA", "BBB", "CCC"))

in_rows(.list = list(a = 1, b = 2, c = 3))
in_rows(1, 2, .list = list(3), .names = c("a", "b", "c"))

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  analyze("AGE", afun = function(x) {
    in_rows(
      "Mean (sd)" = rcell(c(mean(x), sd(x)), format = "xx.xx (xx.xx)"),
      "Range" = rcell(range(x), format = "xx.xx - xx.xx")
    )
  })

tbl <- build_table(lyt, ex_adsl)
tbl

```

is\_rtable

*Check if an object is a valid rtable***Description**

Check if an object is a valid rtable

**Usage**

is\_rtable(x)

**Arguments**

x                    an object

**Value**

TRUE if x is a formal Table object, FALSE otherwise.

**Examples**

is\_rtable(build\_table(basic\_table(), iris))

LabelRow

*Row classes and constructors***Description**

Row classes and constructors

Row constructors and Classes

**Usage**

```
LabelRow(
  lev = 1L,
  label = "",
  name = label,
  vis = !is.na(label) && nzchar(label),
  cinfo = EmptyColInfo,
  indent_mod = 0L,
  table_inset = 0L
)
```

```
.tablerow(
  vals = list(),
  name = "",
  lev = 1L,
  label = name,
  cspan = rep(1L, length(vals)),
  cinfo = EmptyColInfo,
  var = NA_character_,
  format = NULL,
  na_str = NA_character_,
  klass,
  indent_mod = 0L,
  footnotes = list(),
  table_inset = 0L
)
```

```
DataRow(...)
```

```
ContentRow(...)
```

**Arguments**

|       |  |
|-------|--|
| lev   | integer. Nesting level (roughly, indentation level in practical terms).  |
| label | character(1). A label (not to be confused with the name) for the object/structure.   |
| name  | character(1). Name of the split/table/row being created. Defaults to same as the corresponding label, but is not required to be. |

|             |  |
|-------------|--|
| vis         | logical. Should the row be visible (LabelRow only).  |
| cinfo       | InstantiatedColumnInfo (or NULL). Column structure for the object being created.   |
| indent_mod  | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior. |
| table_inset | numeric(1). Number of spaces to inset the table header, table body, referential footnotes, and main_footer, as compared to alignment of title, subtitle, and provenance footer. Defaults to 0 (no inset).  |
| vals        | list. cell values for the row  |
| cspan       | integer. Column span. 1 indicates no spanning.   |
| var         | string, variable name  |
| format      | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| na_str      | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".  |
| klass       | Internal detail.   |
| footnotes   | list or NULL. Referential footnotes to be applied at current level   |
| ...         | passed to shared constructor (.tblerow).   |

**Value**

A formal object representing a table row of the constructed type.

**Author(s)**

Gabriel Becker

---

|               |                      |
|---------------|----------------------|
| label_at_path | <i>Label at Path</i> |
|---------------|----------------------|

---

**Description**

Gets or sets the label at a path

**Usage**

```
label_at_path(tt, path)
```

```
label_at_path(tt, path) <- value
```

**Arguments**

|                    |   |
|--------------------|---|
| <code>tt</code>    | TableTree (or related class). A TableTree object representing a populated table.  |
| <code>path</code>  | character. A vector path for a position within the structure of a tabletree. Each element represents a subsequent choice amongst the children of the previous choice. |
| <code>value</code> | The new value   |

**Details**

If `path` resolves to a single row, the label for that row is retrieved or set. If, instead, `path` resolves to a subtable, the text for the row-label associated with that path is retrieved or set. In the subtable case, if the label text is set to a non-NA value, the labelrow will be set to visible, even if it was not before. Similarly, if the label row text for a subtable is set to NA, the label row will be set to non-visible, so the row will not appear at all when the table is printed.

**Note**

When changing the row labels for content rows, it is important to path all the way to the *row*. Paths ending in "@content" will not exhibit the behavior you want, and are thus an error. See [row\\_paths](#) for help determining the full paths to content rows.

**Examples**

```
lyt <- basic_table() %>%
  split_rows_by("COUNTRY", split_fun = keep_split_levels(c("CHN", "USA"))) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)

label_at_path(tbl, c("COUNTRY", "CHN"))

label_at_path(tbl, c("COUNTRY", "USA")) <- "United States"
tbl
```

---

`length,CellValue-method`

*Length of a Cell value*

---

**Description**

Length of a Cell value

**Usage**

```
## S4 method for signature 'CellValue'
length(x)
```

**Arguments**

x                      x.

**Value**

Always returns 1L

---

|             |   |
|-------------|---|
| list_wrap_x | <i>Returns a function that coerces the return values of f to a list</i> |
|-------------|---|

---

**Description**

Returns a function that coerces the return values of f to a list

**Usage**

```
list_wrap_x(f)
```

```
list_wrap_df(f)
```

**Arguments**

f                      The function to wrap.

**Details**

list\_wrap\_x generates a wrapper which takes x as its first argument, while list\_wrap\_df generates an otherwise identical wrapper function whose first argument is named df.

We provide both because when using the functions as tabulation in [analyze](#), functions which take df as their first argument are passed the full subset dataframe, while those which accept anything else notably including x are passed only the relevant subset of the variable being analyzed.

**Value**

A function which calls f and converts the result to a list of CellValue objects.

**Author(s)**

Gabriel Becker

## Examples

```
summary(iris$Sepal.Length)

f <- list_wrap_x(summary)
f(x = iris$Sepal.Length)

f2 <- list_wrap_df(summary)
f2(df = iris$Sepal.Length)
```

)

```

### Arguments

|              |   |
|--------------|---|
| lyt          | layout object pre-data used for tabulation  |
| var          | string, variable name   |
| vars         | character vector. Multiple variable names.  |
| label        | character(1). A label (not to be confused with the name) for the object/structure.  |
| labels_var   | string, name of variable containing labels to be displayed for the values of var  |
| varlabels    | character vector. Labels for vars   |
| varnames     | character vector. Names for vars which will appear in pathing. When vars are all unique this will be the variable names. If not, these will be variable names with suffixes as necessary to enforce uniqueness.   |
| split_format | FormatSpec. Default format associated with the split being created.   |
| split_na_str | character. NA string vector for use with split_format.  |
| nested       | boolean. Should this layout instruction be applied within the existing layout structure <i>if possible</i> (TRUE, the default) or as a new top-level element ('FALSE'). Ignored if it would nest a split underneath analyses, which is not allowed.                   |
| format       | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.  |
| cfun         | list/function/NULL. tabulation function(s) for creating content rows. Must accept x or df as first parameter. Must accept labelstr as the second argument. Can optionally accept all optional arguments accepted by analysis functions. See <a href="#">analyze</a> . |
| cformat      | format spec. Format for content rows  |
| cna_str      | character. NA string for use with cformat for content table.  |

|              |  |
|--------------|--|
| split_fun    | function/NULL. custom splitting function See <a href="#">custom_split_funs</a>   |
| split_name   | string. Name associated with this split (for pathing, etc)   |
| split_label  | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).  |
| afun         | function. Analysis function, must take x or df as its first parameter. Can optionally take other parameters which will be populated by the tabulation framework. See Details in <a href="#">analyze</a> .  |
| inclNAs      | boolean. Should observations with NA in the var variable(s) be included when performing this analysis. Defaults to FALSE   |
| valorder     | character vector. Order that the split children should appear in resulting table.  |
| ref_group    | character. Value of var to be taken as the ref_group/control to be compared against.   |
| compfun      | function/string. The comparison function which accepts the analysis function outputs for two different partitions and returns a single value. Defaults to subtraction. If a string, taken as the name of a function.   |
| label_fstr   | string. An sprintf style format string containing. For non-comparison splits, it can contain up to one "%s" which takes the current split value and generates the row/column label. Comparison-based splits it can contain up to two "%s".                       |
| child_labels | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.                |
| extra_args   | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function. |
| name         | character(1). Name of the split/table/row being created. Defaults to same as the corresponding label, but is not required to be.   |
| cuts         | numeric. Cuts to use   |
| cutlabels    | character (or NULL). Labels for the cuts   |
| cutfun       | function. Function which accepts the <i>full vector</i> of var values and returns cut points to be used (via cut) when splitting data during tabulation  |
| cutlabelfun  | function. Function which returns either labels for the cuts or NULL when passed the return value of cutfun   |
| cumulative   | logical. Should the cuts be treated as cumulative. Defaults to FALSE   |
| indent_mod   | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.                 |
| show_labels  | character(1). Should the variable labels for corresponding to the variable(s) in vars be visible in the resulting table.   |

|               |  |
|---------------|--|
| label_pos     | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| var_labels    | character. Variable labels for 1 or more variables   |
| cvar          | character(1). The variable, if any, which the content function should accept. Defaults to NA.  |
| table_names   | character. Names for the tables representing each atomic analysis. Defaults to var.  |
| topleft       | character. Override values for the "top left" material to be displayed during printing.  |
| align         | character(1) or NULL. Alignment the value should be rendered with. It defaults to "center" if NULL is used. See <a href="#">rtables_aligns</a> for currently supported alignments.   |
| page_by       | logical(1). Should pagination be forced between different children resulting from this split.  |
| page_prefix   | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table  |
| format_na_str | character(1). String which should be displayed when formatted if this cell's value(s) are all NA.  |
| section_div   | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |
| na_str        | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".  |

**Value**

NULL (this is an argument template dummy function)

Other conventions: [compat\\_args\(\)](#), [constr\\_args\(\)](#), [gen\\_args\(\)](#), [sf\\_args\(\)](#)

---

make\_afun

---

*Create custom analysis function wrapping existing function*

---

**Description**

Create custom analysis function wrapping existing function

**Usage**

```

make_afun(
  fun,
  .stats = NULL,
  .formats = NULL,
  .labels = NULL,
  .indent_mods = NULL,
  .ungroup_stats = NULL,
  .format_na_strs = NULL,
  ...,
  .null_ref_cells = ".in_ref_col" %in% names(formals(fun))
)

```

**Arguments**

|                              |   |
|------------------------------|---|
| <code>fun</code>             | function. The function to be wrapped in a new customized analysis fun. Should return named list.  |
| <code>.stats</code>          | character. Names of elements to keep from <code>fun</code> 's full output.  |
| <code>.formats</code>        | ANY. vector/list of formats to override any defaults applied by <code>fun</code> .  |
| <code>.labels</code>         | character. Vector of labels to override defaults returned by <code>fun</code>   |
| <code>.indent_mods</code>    | integer. Named vector of indent modifiers for the generated rows.   |
| <code>.ungroup_stats</code>  | character. Vector of names, which must match elements of <code>.stats</code>  |
| <code>.format_na_strs</code> | ANY. vector/list of na strings to override any defaults applied by <code>fun</code> .   |
| <code>...</code>             | dots. Additional arguments to <code>fun</code> which effectively become new defaults. These can still be overridden by extra args within a split.   |
| <code>.null_ref_cells</code> | logical(1). Should cells for the reference column be NULL-ed by the returned analysis function. Defaults to TRUE if <code>fun</code> accepts <code>.in_ref_col</code> as a formal argument. Note this argument occurs after <code>...</code> so it must be <i>fully</i> specified by name when set. |

**Value**

A function suitable for use in [analyze](#) with element selection, reformatting, and relabeling performed automatically.

**Note**

setting `.ungroup_stats` to non-null changes the *structure* of the value(s) returned by `fun`, rather than just labeling (`.labels`), formatting (`.formats`), and selecting amongst (`.stats`) them. This means that subsequent `make_afun` calls to customize the output further both can and must operate on the new structure, *NOT* the original structure returned by `fun`. See the final pair of examples below.

---

make\_col\_df

*Column Layout Summary*

---

### Description

Generate a structural summary of the columns of an rtables table and return it as a data.frame.

### Usage

```
make_col_df(tt, colwidths = NULL, visible_only = TRUE)
```

**Arguments**

|              |   |
|--------------|---|
| tt           | ANY. Object representing the table-like object to be summarized.  |
| colwidths    | numeric. Internal detail do not set manually.   |
| visible_only | logical(1). Should only visible aspects of the table structure be reflected in this summary. Defaults to TRUE. May not be supported by all methods. |

**Details**

Used for Pagination

---

|                |   |
|----------------|---|
| make_split_fun | <i>Create a Custom Splitting Function</i> |
|----------------|---|

---

**Description**

Create a Custom Splitting Function

**Usage**

```
make_split_fun(pre = list(), core_split = NULL, post = list())
```

**Arguments**

|            |   |
|------------|---|
| pre        | list. Zero or more functions which operate on the incoming data and return a new data frame that should split via <code>core_split</code> . They will be called on the data in the order they appear in the list.                   |
| core_split | function or NULL. If not NULL, a function which accepts the same arguments <code>do_base_split</code> does, and returns the same type of named list. Custom functions which override this behavior cannot be used in column splits. |
| post       | list. Zero or more functions which should be called on the list output by splitting.  |

**Details**

Custom split functions can be thought of as (up to) 3 different types of manipulations of the splitting process

1. Preprocessing of the incoming data to be split
2. (Row-splitting only) Customization of the core mapping of incoming data to facets, and
3. Postprocessing operations on the set of facets (groups) generated by the split.

This function provides an interface to create custom split functions by implementing and specifying sets of operations in each of those classes of customization independently.

Preprocessing functions (1), must accept: `df`, `spl`, `vals`, `labels`, and can optionally accept `.spl_context`. They then manipulate `df` (the incoming data for the split) and return a modified `data.frame`. This modified `data.frame` *must* contain all columns present in the incoming `data.frame`, but can add

columns if necessary (though we note that these new columns cannot be used in the layout as split or analysis variables, because they will not be present when validity checking is done).

The preprocessing component is useful for things such as manipulating factor levels, e.g., to trim unobserved ones or to reorder levels based on observed counts, etc.

Customization of core splitting (2) is currently only supported in row splits. Core splitting functions override the fundamental splitting procedure, and are only necessary in rare cases. These must accept `spl`, `df`, `vals`, `labels`, and can optionally accept `.spl_context`. They must return a named list with elements, all of the same length, as follows: - `datasplit` (containing a list of data.frames), - `values` containing values associated with the facets, which must be character or `SplitValue` objects. These values will appear in the paths of the resulting table. - `labels` containing the character labels associated with values

Postprocessing functions (3) must accept the result of the core split as their first argument (which as of writing can be anything), in addition to `spl`, and `fulldf`, and can optionally accept `.spl_context`. They must each return a modified version of the same structure specified above for core splitting.

In both the pre- and post-processing cases, multiple functions can be specified. When this happens, they are applied sequentially, in the order they appear in the list passed to the relevant argument (pre and post, respectively).

## Value

A function for use as a custom split function.

## See Also

[custom\\_split\\_funs](#) for a more detailed discussion on what custom split functions do.

Other `make_custom_split`: [add\\_combo\\_facet\(\)](#), [drop\\_facet\\_levels\(\)](#), [make\\_split\\_result\(\)](#), [trim\\_levels\\_in\\_facets\(\)](#)

## Examples

```
mysplitfun <- make_split_fun(pre = list(drop_facet_levels),
  post = list(add_overall_facet("ALL", "All Arms")))

basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM", split_fun = mysplitfun) %>%
  analyze("AGE") %>%
  build_table(subset(DM, ARM %in% c("B: Placebo", "C: Combination"))

## post (and pre) arguments can take multiple functions, here
## we add an overall facet and the reorder the facets
reorder_facets <- function(splret, spl, fulldf, ...) {
  ord <- order(names(splret$values))
  make_split_result(splret$values[ord],
    splret$datasplit[ord],
    splret$labels[ord])
}
```

```

mysplitfun2 <- make_split_fun(pre = list(drop_facet_levels),
                             post = list(add_overall_facet("ALL", "All Arms"),
                                         reorder_facets))
basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM", split_fun = mysplitfun2) %>%
  analyze("AGE") %>%
  build_table(subset(DM, ARM %in% c("B: Placebo", "C: Combination")))

very_stupid_core <- function(spl, df, vals, labels, .spl_context) {
  make_split_result(c("stupid", "silly"),
                   datasplit = list(df[1:10,], df[11:30,]),
                   labels = c("first 10", "second 20"))
}

dumb_30_facet <- add_combo_facet("dumb",
                                label = "thirty patients",
                                levels = c("stupid", "silly"))
nonsense_splfun <- make_split_fun(core_split = very_stupid_core,
                                 post = list(dumb_30_facet))

## recall core split overriding is not supported in column space
## currently, but we can see it in action in row space

lyt_silly <- basic_table() %>%
  split_rows_by("ARM", split_fun = nonsense_splfun) %>%
  summarize_row_groups() %>%
  analyze("AGE")
silly_table <- build_table(lyt_silly, DM)
silly_table

```

---

make\_split\_result      *Construct split result object*

---

### Description

These functions can be used to create or add to a split result in functions which implement core splitting or post-processing within a custom split function.

### Usage

```
make_split_result(values, datasplit, labels, extras = NULL)
```

```
add_to_split_result(splres, values, datasplit, labels, extras = NULL)
```

### Arguments

|           |  |
|-----------|--|
| values    | character or list(SplitValue). The values associated with each facet   |
| datasplit | list(data.frame). The facet data for each facet generated in the split |
| labels    | character. The labels associated with each facet                       |

|        |  |
|--------|--|
| extras | NULL or list. Extra values associated with each of the facets which will be passed to analysis functions applied within the facet. |
| splres | list. A list representing the result of splitting.   |

### Details

These functions does various housekeeping to ensure that the split result list is as the rtables internals expect it, most of which are not relevant to end users.

### Value

a named list representing the facets generated by the split with elements values, datasplit, and labels, which are the same length and correspond to eachother elementwise.

### See Also

Other make\_custom\_split: [add\\_combo\\_facet\(\)](#), [drop\\_facet\\_levels\(\)](#), [make\\_split\\_fun\(\)](#), [trim\\_levels\\_in\\_facets\(\)](#)

### Examples

```
splres <- make_split_result(values = c("hi", "lo"),
  datasplit = list(hi = mtcars, lo = mtcars[1:10,]),
  labels = c("more data", "less data"))

splres2 <- add_to_split_result(splres,
  values = "med",
  datasplit = list(med = mtcars[1:20,]),
  labels = "kinda some data")
```

---

ManualSplit

*Manually defined split*

---

### Description

Manually defined split

### Usage

```
ManualSplit(
  levels,
  label,
  name = "manual",
  extra_args = list(),
  indent_mod = 0L,
  cindent_mod = 0L,
  cvar = "",
  cextra_args = list(),
  label_pos = "visible",
```

```

    page_prefix = NA_character_,
    section_div = NA_character_
  )

```

### Arguments

|             |  |
|-------------|--|
| levels      | character. Levels of the split (ie the children of the manual split)   |
| label       | character(1). A label (not to be confused with the name) for the object/structure.   |
| name        | character(1). Name of the split/table/row being created. Defaults to same as the corresponding label, but is not required to be.   |
| extra_args  | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function.   |
| indent_mod  | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.   |
| cindent_mod | numeric(1). The indent modifier for the content tables generated by this split.  |
| cvar        | character(1). The variable, if any, which the content function should accept. Defaults to NA.  |
| cextra_args | list. Extra arguments to be passed to the content function when tabulating row group summaries.  |
| label_pos   | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| page_prefix | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table  |
| section_div | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |

### Value

A ManualSplit object.

### Author(s)

Gabriel Becker

---

`manual_cols`*Manual column declaration*

---

**Description**

Manual column declaration

**Usage**

```
manual_cols(..., .lst = list(...))
```

**Arguments**

`...` One or more vectors of levels to appear in the column space. If more than one set of levels is given, the values of the second are nested within each value of the first, and so on.

`.lst` A list of sets of levels, by default populated via `list(...)`.

**Value**

An `InstantiatedColumnInfo` object, suitable for use declaring the column structure for a manually constructed table.

**Author(s)**

Gabriel Becker

**Examples**

```
# simple one level column space
rows <- lapply(1:5, function(i) {
  DataRow(rep(i, times = 3)))
tbl <- TableTree(kids = rows, cinfo = manual_cols(split = c("a", "b", "c")))
tbl

# manually declared nesting
tbl2 <- TableTree(kids = list(DataRow(as.list(1:4))),
  cinfo = manual_cols(Arm = c("Arm A", "Arm B"),
    Gender = c("M", "F")))
tbl2
```

---

 matrix\_form, VTableTree-method

*Transform rtable to a list of matrices which can be used for outputting*

---

## Description

Although rtables are represented as a tree data structure when outputting the table to ASCII or HTML it is useful to map the rtable to an in between state with the formatted cells in a matrix form.

## Usage

```
## S4 method for signature 'VTableTree'
matrix_form(
  obj,
  indent_rownames = FALSE,
  expand_newlines = TRUE,
  indent_size = 2
)
```

## Arguments

|                 |   |
|-----------------|---|
| obj             | ANY. The object for the accessor to access or modify  |
| indent_rownames | logical(1), if TRUE the column with the row names in the strings matrix of has indented row names (strings pre-fixed)   |
| expand_newlines | logical(1). Should the matrix form generated expand rows whose values contain newlines into multiple 'physical' rows (as they will appear when rendered into ASCII). Defaults to TRUE |
| indent_size     | numeric(1). Number of spaces to use per indent level. Defaults to 2   |

## Details

The strings in the return object are defined as follows: row labels are those determined by `make_row_df` and cell values are determined using `get_formatted_cells`. (Column labels are calculated using a non-exported internal function.

## Value

A list with the following elements:

- strings** The content, as it should be printed, of the top-left material, column headers, row labels , and cell values of `tt`
- spans** The column-span information for each print-string in the strings matrix
- aligns** The text alignment for each print-string in the strings matrix
- display** Whether each print-string in the strings matrix should be printed or not.

**row\_info** the data.frame generated by `make_row_df`

With an additional `nrow_header` attribute indicating the number of pseudo "rows" the column structure defines.

### Examples

```
library(dplyr)

iris2 <- iris %>%
  group_by(Species) %>%
  mutate(group = as.factor(rep_len(c("a", "b"), length.out = n()))) %>%
  ungroup()

lyt <- basic_table() %>%
  split_cols_by("Species") %>%
  split_cols_by("group") %>%
  analyze(c("Sepal.Length", "Petal.Width"),
         afun = list_wrap_x(summary) , format = "xx.xx")

lyt

tbl <- build_table(lyt, iris2)

matrix_form(tbl)
```

---

MultiVarSplit

*Split between two or more different variables*

---

### Description

Split between two or more different variables

### Usage

```
MultiVarSplit(
  vars,
  split_label = "",
  varlabels = NULL,
  varnames = NULL,
  cfun = NULL,
  cformat = NULL,
  cna_str = NA_character_,
  split_format = NULL,
  split_na_str = NA_character_,
  split_name = "multivars",
  child_labels = c("default", "visible", "hidden"),
  extra_args = list(),
  indent_mod = 0L,
```

```

    cindent_mod = 0L,
    cvar = "",
    cextra_args = list(),
    label_pos = "visible",
    split_fun = NULL,
    page_prefix = NA_character_,
    section_div = NA_character_
  )

```

## Arguments

|                           |  |
|---------------------------|--|
| <code>vars</code>         | character vector. Multiple variable names.   |
| <code>split_label</code>  | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).  |
| <code>varlabels</code>    | character vector. Labels for vars  |
| <code>varnames</code>     | character vector. Names for vars which will appear in pathing. When vars are all unique this will be the variable names. If not, these will be variable names with suffixes as necessary to enforce uniqueness.  |
| <code>cfun</code>         | list/function/NULL. tabulation function(s) for creating content rows. Must accept <code>x</code> or <code>df</code> as first parameter. Must accept <code>labelstr</code> as the second argument. Can optionally accept all optional arguments accepted by analysis functions. See <a href="#">analyze</a> . |
| <code>cformat</code>      | format spec. Format for content rows   |
| <code>cna_str</code>      | character. NA string for use with <code>cformat</code> for content table.  |
| <code>split_format</code> | FormatSpec. Default format associated with the split being created.  |
| <code>split_na_str</code> | character. NA string vector for use with <code>split_format</code> .   |
| <code>split_name</code>   | string. Name associated with this split (for pathing, etc)   |
| <code>child_labels</code> | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.  |
| <code>extra_args</code>   | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function.   |
| <code>indent_mod</code>   | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.   |
| <code>cindent_mod</code>  | numeric(1). The indent modifier for the content tables generated by this split.  |
| <code>cvar</code>         | character(1). The variable, if any, which the content function should accept. Defaults to NA.  |
| <code>cextra_args</code>  | list. Extra arguments to be passed to the content function when tabulating row group summaries.  |

|             |  |
|-------------|--|
| label_pos   | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| split_fun   | function/NULL. custom splitting function See <a href="#">custom_split_funs</a>   |
| page_prefix | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table  |
| section_div | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |

**Value**

A MultiVarSplit object.

**Author(s)**

Gabriel Becker

---

names, VTableNodeInfo-method

*Names of a TableTree*

---

**Description**

Names of a TableTree

**Usage**

```
## S4 method for signature 'VTableNodeInfo'
names(x)
```

```
## S4 method for signature 'InstantiatedColumnInfo'
names(x)
```

```
## S4 method for signature 'LayoutColTree'
names(x)
```

```
## S4 method for signature 'VTableTree'
row.names(x)
```

**Arguments**

x                    the object.

**Details**

For TableTrees with more than one level of splitting in columns, the names are defined to be the top-level split values repped out across the columns that they span.

**Value**

The column names of x, as defined in the details above.

---

|            |                                 |
|------------|---------------------------------|
| no_colinfo | <i>Exported for use in tern</i> |
|------------|---------------------------------|

---

**Description**

Does the table/row/InstantiatedColumnInfo object contain no column structure information?

**Usage**

```
no_colinfo(obj)

## S4 method for signature 'VTableNodeInfo'
no_colinfo(obj)

## S4 method for signature 'InstantiatedColumnInfo'
no_colinfo(obj)
```

**Arguments**

obj                    ANY. The object for the accessor to access or modify

**Value**

TRUE if the object has no/empty instantiated column information, FALSE otherwise.

---

|                         |                         |

)

```

### Arguments

|              |   |
|--------------|---|
| obj          | ANY. The object for the accessor to access or modify  |
| value        | The new value   |
| x            | An object   |
| colwidths    | numeric vector. Column widths for use with vertical pagination.   |
| max_width    | numeric(1). Width strings should be wrapped to when determining how many lines they require.  |
| tt           | TableTree (or related class). A TableTree object representing a populated table.  |
| visible_only | logical(1). Should only visible aspects of the table structure be reflected in this summary. Defaults to TRUE. May not be supported by all methods.                   |
| rownum       | numeric(1). Internal detail do not set manually.  |
| indent       | integer(1). Internal detail do not set manually.  |
| path         | character. A vector path for a position within the structure of a tabletree. Each element represents a subsequent choice amongst the children of the previous choice. |
| incontent    | logical(1). Internal detail do not set manually.  |
| repr_ext     | integer(1). Internal detail do not set manually.  |
| repr_inds    | integer. Internal detail do not set manually.   |
| sibpos       | integer(1). Internal detail do not set manually.  |
| nsibs        | integer(1). Internal detail do not set manually.  |

### Details

When `visible_only` is TRUE (the default), methods should return a data.frame with exactly one row per visible row in the table-like object. This is useful when reasoning about how a table will print, but does not reflect the full pathing space of the structure (though the paths which are given will all work as is).

If supported, when `visible_only` is FALSE, every structural element of the table (in row-space) will be reflected in the returned data.frame, meaning the full pathing-space will be represented but some rows in the layout summary will not represent printed rows in the table as it is displayed.

Most arguments beyond `tt` and `visible_only` are present so that `make_row_df` methods can call `make_row_df` recursively and retain information, and should not be set during a top-level call

**Value**

for getters, the current value of the component being accessed on obj, for setters, a modified copy of obj with the new value.

**Note**

the technically present root tree node is excluded from the summary returned by both `make_row_df` and `make_col_df`, as it is simply the row/column structure of `tt` and thus not useful for pathing or pagination.

---

pag\_tt\_indices

*Pagination of a TableTree*

---

**Description**

Paginate an `rtables` table in the vertical and/or horizontal direction, as required for the specified page size.

**Usage**

```
pag_tt_indices(
  tt,
  lpp = 15,
  min_siblings = 2,
  nosplitin = character(),
  colwidths = NULL,
  max_width = NULL,
  verbose = FALSE
)

paginate_table(
  tt,
  page_type = "letter",
  font_family = "Courier",
  font_size = 8,
  lineheight = 1,
  landscape = FALSE,
  pg_width = NULL,
  pg_height = NULL,
  margins = c(top = 0.5, bottom = 0.5, left = 0.75, right = 0.75),
  lpp = NA_integer_,
  cpp = NA_integer_,
  min_siblings = 2,
  nosplitin = character(),
  colwidths = NULL,
  tf_wrap = FALSE,
  max_width = NULL,
```

```

    verbose = FALSE
  )

```

### Arguments

|              |  |
|--------------|--|
| tt           | TableTree (or related class). A TableTree object representing a populated table.   |
| lpp          | numeric. Maximum lines per page including (re)printed header and context rows  |
| min_siblings | numeric. Minimum sibling rows which must appear on either side of pagination row for a mid-subtable split to be valid. Defaults to 2.  |
| nosplitin    | character. List of names of sub-tables where page-breaks are not allowed, regardless of other considerations. Defaults to none.  |
| colwidths    | numeric vector. Column widths for use with vertical pagination.  |
| max_width    | integer(1), character(1) or NULL. Width that title and footer (including footnotes) materials should be word-wrapped to. If NULL, it is set to the current print width of the session ( <code>getOption("width")</code> ). If set to "auto", the width of the table (plus any table inset) is used. Ignored completely if <code>tf_wrap</code> is FALSE. |
| verbose      | logical(1). Should extra debugging messages be shown. Defaults to FALSE.   |
| page_type    | character(1). Name of a page type. See <code>page_types</code> . Ignored when <code>pg_width</code> and <code>pg_height</code> are set directly.   |
| font_family  | character(1). Name of a font family. An error will be thrown if the family named is not monospaced. Defaults to Courier.   |
| font_size    | numeric(1). Font size, defaults to 12.   |
| lineheight   | numeric(1). Line height, defaults to 1.  |
| landscape    | logical(1). Should the dimensions of <code>page_type</code> be inverted for landscape? Defaults to FALSE, ignored when <code>pg_width</code> and <code>pg_height</code> are set directly.  |
| pg_width     | numeric(1). Page width in inches.  |
| pg_height    | numeric(1). Page height in inches.   |
| margins      | numeric(4). Named numeric vector containing 'bottom', 'left', 'top', and 'right' margins in inches. Defaults to .5 inches for both vertical margins and .75 for both horizontal margins.   |
| cpp          | numeric(1) or NULL. Width (in characters) of the pages for horizontal pagination. NA (the default) indicates <code>cpp</code> should be inferred from the page size; NULL indicates no horizontal pagination should be done regardless of page size.   |
| tf_wrap      | logical(1). Should the texts for title, subtitle, and footnotes be wrapped?  |

### Details

`rtables` pagination is context aware, meaning that label rows and row-group summaries (content rows) are repeated after (vertical) pagination, as appropriate. This allows the reader to immediately understand where they are in the table after turning to a new page, but does also mean that a rendered, paginated table will take up more lines of text than rendering the table without pagination would.

Pagination also takes into account word-wrapping of title, footer, column-label, and formatted cell value content.

Vertical pagination information (pagination dataframe) is created using (make\_row\_df)

Horizontal pagination is performed by creating a pagination dataframe for the columns, and then applying the same algorithm used for vertical pagination to it.

If physical page size and font information are specified, these are used to derive lines-per-page (lpp) and characters-per-page (cpp) values.

The full multi-direction pagination algorithm then is as follows:

1. Adjust lpp and cpp to account for rendered elements that are not rows (columns)
  - titles/footers/column labels, and horizontal dividers in the vertical pagination case
  - row-labels, table\_inset, and top-left materials in the horizontal case
1. Perform 'forced pagination' representing page-by row splits, generating 1 or more tables
2. Perform vertical pagination separately on each table generated in (1)
3. Perform horizontal pagination **on the entire table** and apply the results to each table page generated in (1)-(2)
4. Return a list of subtables representing full bi-directional pagination

Pagination in both directions is done using the *Core Pagination Algorithm* implemented in the formatters package:

## Value

for pag\_tt\_indices a list of paginated-groups of row-indices of tt. For paginate\_table, The subtables defined by subsetting by the indices defined by pag\_tt\_indices.

## Pagination Algorithm

Pagination is performed independently in the vertical and horizontal directions based solely on a *pagination dataframe*, which includes the following information for each row/column:

- number of lines/characters rendering the row will take **after word-wrapping** (self\_extent)
- the indices (reprint\_inds) and number of lines (par\_extent) of the rows which act as **context** for the row
- the row's number of siblings and position within its siblings

Given lpp (cpp) already adjusted for rendered elements which are not rows/columns and a dataframe of pagination information, pagination is performed via the following algorithm, and with a start = 1:

Core Pagination Algorithm:

1. Initial guess for pagination point is start + lpp (start + cpp)
2. While the guess is not a valid pagination position, and guess > start, decrement guess and repeat

- an error is thrown if all possible pagination positions between start and start + lpp (start + cpp) would ever be < start after decrementing
1. Retain pagination index
  2. if pagination point was less than NROW(tt) (ncol(tt)), set start to pos + 1, and repeat steps (1) - (4).

Validating pagination position:

Given an (already adjusted) lpp or cpp value, a pagination is invalid if:

- The rows/columns on the page would take more than (adjusted) lpp lines/cpp characters to render **including**
  - word-wrapping
  - (vertical only) context repetition
- (vertical only) footnote messages and or section divider lines take up too many lines after rendering rows
- (vertical only) row is a label or content (row-group summary) row
- (vertical only) row at the pagination point has siblings, and it has less than min\_siblings preceding or following siblings
- pagination would occur within a sub-table listed in nosplitin

## Examples

```
s_summary <- function(x) {
  if (is.numeric(x)) {
    in_rows(
      "n" = rcell(sum(!is.na(x)), format = "xx"),
      "Mean (sd)" = rcell(c(mean(x, na.rm = TRUE), sd(x, na.rm = TRUE)),
        format = "xx.xx (xx.xx)"),
      "IQR" = rcell(IQR(x, na.rm = TRUE), format = "xx.xx"),
      "min - max" = rcell(range(x, na.rm = TRUE), format = "xx.xx - xx.xx")
    )
  } else if (is.factor(x)) {
    vs <- as.list(table(x))
    do.call(in_rows, lapply(vs, rcell, format = "xx"))
  } else (
    stop("type not supported")
  )
}

lyt <- basic_table() %>%
split_cols_by(var = "ARM") %>%
  analyze(c("AGE", "SEX", "BEP01FL", "BMRKR1", "BMRKR2", "COUNTRY"), afun = s_summary)

tbl <- build_table(lyt, ex_adsl)
```

```
tbl

nrow(tbl)

row_paths_summary(tbl)

tbls <- paginate_table(tbl, lpp = 15)
mf <- matrix_form(tbl, indent_rownames = TRUE)
w_tbls <- propose_column_widths(mf) # so that we have the same column widths

tmp <- lapply(tbls, function(tbli) {
  cat(toString(tbli, widths = w_tbls))
  cat("\n\n")
  cat("~~~~~ PAGE BREAK ~~~~~")
  cat("\n\n")
})
```

---

path\_enriched\_df

*Transform TableTree object to Path-Enriched data.frame*

---

## Description

Transform TableTree object to Path-Enriched data.frame

## Usage

```
path_enriched_df(tt, path_fun = collapse_path, value_fun = collapse_values)
```

## Arguments

|           |  |
|-----------|--|
| tt        | TableTree (or related class). A TableTree object representing a populated table.   |
| path_fun  | function. Function to transform paths into single-string row/column names.   |
| value_fun | function. Function to transform cell values into cells of the data.frame. Defaults to collapse_values which creates strings where multi-valued cells are collapsed together, separated by  . |

## Value

A data frame of tt's cell values (processed by value\_fun, with columns named by the full column paths (processed by path\_fun and an additional row\_path column with the row paths (processed by path\_fun)).

## Examples

```
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  analyze(c("AGE", "BMRKR2"))

tbl <- build_table(lyt, ex_adsl)
path_enriched_df(tbl)
```

---

|             |                                      |
|-------------|--------------------------------------|
| prune_table | <i>Recursively prune a TableTree</i> |
|-------------|--------------------------------------|

---

## Description

Recursively prune a TableTree

## Usage

```
prune_table(
  tt,
  prune_func = prune_empty_level,
  stop_depth = NA_real_,
  depth = 0
)
```

## Arguments

|            |  |
|------------|--|
| tt         | TableTree (or related class). A TableTree object representing a populated table.   |
| prune_func | function. A Function to be called on each subtree which returns TRUE if the entire subtree should be removed.                                    |
| stop_depth | numeric(1). The depth after which subtrees should not be checked for pruning. Defaults to NA which indicates pruning should happen at all levels |
| depth      | numeric(1). Used internally, not intended to be set by the end user.   |

## Value

A TableTree pruned via recursive application of prune\_func.

## See Also

[prune\\_empty\\_level\(\)](#) for details on this and several other basic pruning functions included in the rtables package.

**Examples**

```

adsl <- ex_adsl
levels(adsl$SEX) <- c(levels(ex_adsl$SEX), "OTHER")

tbl_to_prune <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX") %>%
  summarize_row_groups() %>%
  split_rows_by("STRATA1") %>%
  summarize_row_groups() %>%
  analyze("AGE") %>%
  build_table(adsl)

tbl_to_prune %>% prune_table()

```

---

rbindl\_rtables

*rbind TableTree and related objects*

---

**Description**

rbind TableTree and related objects

**Usage**

```

rbindl_rtables(x, gap = 0, check_headers = TRUE)

## S4 method for signature 'VTableNodeInfo'
rbind(..., deparse.level = 1)

## S4 method for signature 'VTableNodeInfo,ANY'
rbind2(x, y)

```

**Arguments**

|               |  |
|---------------|--|
| x             | VTableNodeInfo. TableTree, ElementaryTable or TableRow object. |
| gap           | deprecated. Ignored.   |
| check_headers | deprecated. Ignored.   |
| ...           | ANY. Elements to be stacked.                                   |
| deparse.level | numeric(1). Currently Ignored.                                 |
| y             | VTableNodeInfo. TableTree, ElementaryTable or TableRow object. |

**Value**

A formal table object.

**Examples**

```

mtbl <- rtable(
  header = rheader(
    row(row.name = NULL, rcell("Sepal.Length", colspan = 2), rcell("Petal.Length", colspan=2)),
    rrow(NULL, "mean", "median", "mean", "median")
  ),
  rrow(
    row.name = "All Species",
    mean(iris$Sepal.Length), median(iris$Sepal.Length),
    mean(iris$Petal.Length), median(iris$Petal.Length),
    format = "xx.xx"
  )
)

mtbl2 <- with(subset(iris, Species == 'setosa'), rtable(
  header = rheader(
    row(row.name = NULL, rcell("Sepal.Length", colspan = 2), rcell("Petal.Length", colspan=2)),
    rrow(NULL, "mean", "median", "mean", "median")
  ),
  rrow(
    row.name = "Setosa",
    mean(Sepal.Length), median(Sepal.Length),
    mean(Petal.Length), median(Petal.Length),
    format = "xx.xx"
  )
))

rbind(mtbl, mtbl2)
rbind(mtbl, rrow(), mtbl2)
rbind(mtbl, rrow("aaa"), indent(mtbl2))

```

---

rcell

*Cell value constructors*

---

**Description**

Construct a cell value and associate formatting, labeling, indenting, and column spanning information with it.

**Usage**

```

rcell(
  x,
  format = NULL,
  colspan = 1L,
  label = NULL,
  indent_mod = NULL,
  footnotes = NULL,
  align = NULL,

```

```

    format_na_str = NULL
  )

non_ref_rcell(
  x,
  is_ref,
  format = NULL,
  colspan = 1L,
  label = NULL,
  indent_mod = NULL,
  refval = NULL,
  align = "center",
  format_na_str = NULL
)

```

### Arguments

|               |  |
|---------------|--|
| x             | ANY. Cell value.   |
| format        | character(1) or function. The format label (string) or formatter function to apply to x. See <a href="#">list_valid_format_labels</a> for currently supported format labels.   |
| colspan       | integer(1). Column span value.   |
| label         | character(1). Label or NULL. If non-null, it will be looked at when determining row labels.  |
| indent_mod    | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior. |
| footnotes     | list or NULL. Referential footnote messages for the cell.  |
| align         | character(1) or NULL. Alignment the value should be rendered with. It defaults to "center" if NULL is used. See <a href="#">rtables_aligns</a> for currently supported alignments.   |
| format_na_str | character(1). String which should be displayed when formatted if this cell's value(s) are all NA.  |
| is_ref        | logical(1). Are we in the reference column (ie .in_ref_col should be passed to this argument)  |
| refval        | ANY. Value to use when in the reference column. Defaults to NULL   |

### Details

non\_ref\_rcell provides the common *blank for cells in the reference column, this value otherwise*, and should be passed the value of .in\_ref\_col when it is used.

### Value

An object representing the value within a single cell within a populated table. The underlying structure of this object is an implementation detail and should not be relied upon beyond calling accessors for the class.

**Note**

Currently column spanning is only supported for defining header structure.

---

|         |                        |
|---------|------------------------|
| rheader | <i>Create a header</i> |
|---------|------------------------|

---

**Description**

Create a header

**Usage**

```
rheader(..., format = "xx", .lst = NULL)
```

**Arguments**

|        |   |
|--------|---|
| ...    | row specifications (either as character vectors or the output from <code>rrow</code> or <code>DataRow</code> , <code>LabelRow</code> , etc.   |
| format | character(1) or function. The format label (string) or formatter function to apply to the cell values passed via .... See <a href="#">list_valid_format_labels</a> for currently supported format labels. |
| .lst   | list. An already-collected list of arguments to be used instead of the elements of .... Arguments passed via ... will be ignored if this is specified.  |

**Value**

a `InstantiatedColumnInfo` object.

**See Also**

Other compatibility: `rrow1()`, `rrow()`, `rtable()`

**Examples**

```
h1 <- rheader(c("A", "B", "C"))

h2 <- rheader(
  rrow(NULL, rcell("group 1", colspan = 2), rcell("group 2", colspan = 2)),
  rrow(NULL, "A", "B", "A", "B")
)

h1

h2
```

---

|               |                                       |
|---------------|---------------------------------------|
| row_footnotes | <i>Referential Footnote Accessors</i> |
|---------------|---------------------------------------|

---

### Description

Get and set referential footnotes on aspects of a built table

### Usage

```
row_footnotes(obj)

row_footnotes(obj) <- value

cell_footnotes(obj)

cell_footnotes(obj) <- value

col_fnotes_here(obj)

col_fnotes_here(obj) <- value

ref_index(obj)

ref_index(obj) <- value

ref_symbol(obj)

ref_symbol(obj) <- value

ref_msg(obj)

fnotes_at_path(obj, rowpath = NULL, colpath = NULL, reset_idx = TRUE) <- value
```

### Arguments

|           |   |
|-----------|---|
| obj       | ANY. The object for the accessor to access or modify  |
| value     | The new value   |
| rowpath   | character or NULL. Path within row structure. NULL indicates the footnote should go on the column rather than cell. |
| colpath   | character or NULL. Path within column structure. NULL indicates footnote should go on the row rather than cell      |
| reset_idx | logical(1). Should the numbering for referential footnotes be immediately recalculated. Defaults to TRUE.           |

# tbl
```

---

row\_paths

*Return List with Table Row/Col Paths*

---

## Description

Return List with Table Row/Col Paths

## Usage

```
row_paths(x)
```

```
col_paths(x)
```

## Arguments

x                    an rtable object

## Value

a list of paths to each row/column within x

## See Also

  split_cols_by("ARM") %>%
  analyze(c("SEX", "AGE"))

tbl <- build_table(lyt, ex_adsl)
tbl

row_paths(tbl)
col_paths(tbl)

cell_values(tbl, c("AGE", "Mean"), c("ARM", "B: Placebo"))
```

---

row\_paths\_summary      *Print Row/Col Paths Summary*

---

**Description**

Print Row/Col Paths Summary

**Usage**

```
row_paths_summary(x)

col_paths_summary(x)
```

**Arguments**

x                    an rtable object

**Value**

A data.frame summarizing the row- or column-structure of x.

**Examples**

```
library(dplyr)

ex_adsl_MF <- ex_adsl %>% filter(SEX %in% c("M", "F"))

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%

rrow

*rrow*

---

## Description

row

## Usage

```
rrow(row.name = "", ..., format = NULL, indent = 0, inset = 0L)
```

## Arguments

|          |   |
|----------|---|
| row.name | if NULL then an empty string is used as row.name of the <a href="#">rrow</a> .  |
| ...      | cell values   |
| format   | character(1) or function. The format label (string) or formatter function to apply to the cell values passed via .... See <a href="#">list_valid_format_labels</a> for currently supported format labels. |
| indent   | deprecated.   |
| inset    | integer(1). The table inset for the row or table being constructed. See <a href="#">table_inset</a> .   |

## Value

A row object of the context-appropriate type (label or data)

## See Also

Other compatibility: [rheader\(\)](#), [rrow1\(\)](#), [rtable\(\)](#)

**Examples**

```
rrowl("ABC", c(1,2), c(3,2), format = "xx (xx.%)")
rrowl("")
```

---

rrowl

*rrowl*

---

**Description**

rrowl

**Usage**

```
rrowl(row.name, ..., format = NULL, indent = 0, inset = 0L)
```

**Arguments**

|          |   |
|----------|---|
| row.name | if NULL then an empty string is used as row.name of the <a href="#">rrow</a> .  |
| ...      | values in vector/list form  |
| format   | character(1) or function. The format label (string) or formatter function to apply to the cell values passed via .... See <a href="#">list_valid_format_labels</a> for currently supported format labels. |
| indent   | deprecated.   |
| inset    | integer(1). The table inset for the row or table being constructed. See <a href="#">table_inset</a> .   |

**Value**

A row object of the context-appropriate type (label or data)

**See Also**

Other compatibility: [rheader\(\)](#), [rrow\(\)](#), [rtable\(\)](#)

**Examples**

```
rrowl("a", c(1,2,3), format = "xx")
rrowl("a", c(1,2,3), c(4,5,6), format = "xx")

rrowl("N", table(iris$Species))
rrowl("N", table(iris$Species), format = "xx")

x <- tapply(iris$Sepal.Length, iris$Species, mean, simplify = FALSE)

rrow(row.name = "row 1", x)
```

```
rrow("ABC", 2, 3)

rrowl(row.name = "row 1", c(1, 2), c(3,4))
rrow(row.name = "row 2", c(1, 2), c(3,4))
```

---

|        |                       |
|--------|-----------------------|
| rtable | <i>Create a Table</i> |
|--------|-----------------------|

---

## Description

Create a Table

## Usage

```
rtable(header, ..., format = NULL, hsep = default_hsep(), inset = 0L)

rtablel(header, ..., format = NULL, hsep = default_hsep(), inset = 0L)
```

## Arguments

|        |  |
|--------|--|
| header | Information defining the header (column structure) of the table. This can be as row objects (legacy), character vectors or a <code>InstantiatedColumnInfo</code> object.   |
| ...    | Rows to place in the table.  |
| format | character(1) or function. The format label (string) or formatter function to apply to the cell values passed via .... See <a href="#">list_valid_format_labels</a> for currently supported format labels.  |
| hsep   | character(1). Set of character(s) to be repeated as the separator between the header and body of the table when rendered as text. Defaults to a connected horizontal line (unicode 2014) in locals that use a UTF charset, and to - elsewhere (with a once per session warning). |
| inset  | integer(1). The table inset for the row or table being constructed. See <a href="#">table_inset</a> .  |

## Value

a formal table object of the appropriate type (`ElementaryTable` or `TableTree`)

## See Also

Other compatibility: [rheader\(\)](#), [rrowl\(\)](#), [rrow\(\)](#)

**Examples**

```

rtables\_aligns

*Alignment utils*

---

### **Description**

Currently supported cell value alignments. These values may be used to set content alignment (align in [rcell\(\)](#) or .aligns in [in\\_rows\(\)](#)).

### **Usage**

```
rtables_aligns()
```

### **Value**

a vector of alignments currently supported.

### **See Also**

[in\\_rows\(\)](#), [rcell\(\)](#)

**Examples**

```

# See the alignments available in rtables
rtables_aligns()

# Right alignment with align in rcell()
lyt <- basic_table() %>%
  analyze("Species", function(x) in_rows(left = rcell("r", align = "right")))

tbl <- build_table(lyt, iris)
tbl

# Set multiple alignments using character vectors with .aligns in in_rows()
lyt2 <- basic_table() %>%
  analyze("Species", function(x) {
    in_rows(
      left = rcell("l"),
      right = rcell("r"),
      .aligns = c("left", "right")
    )
  })

tbl2 <- build_table(lyt2, iris)
tbl2

# Clinical data example:
lyt3 <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX", split_fun = drop_split_levels) %>%
  analyze(c("AGE"), function(x) {
    in_rows(
      "mean" = rcell(mean(x), align = "right"),
      "sd" = rcell(sd(x), align = "left"), .formats = c("xx.x")
    )
  }, show_labels = "visible", na_str = "NE")

tbl3 <- build_table(lyt3, ex_adsl)
tbl3

```

---

select\_all\_levels      *Add Combination Levels to split*

---

**Description**

Add Combination Levels to split

**Usage**

```
select_all_levels
```

```
add_combo_levels(combosdf, trim = FALSE, first = FALSE, keep_levels = NULL)
```

**Arguments**

|             |  |
|-------------|--|
| combosdf    | data.frame/tbl_df. Columns valname, label, levelcombo, exargs. Of which levelcombo and exargs are list columns. Passing the select_all_levels object as a value in the comblevels column indicates that an overall/all-observations level should be created. |
| trim        | logical(1). Should splits corresponding with 0 observations be kept when tabulating.   |
| first       | logical(1). Should the created split level be placed first in the levels (TRUE) or last (FALSE, the default).  |
| keep_levels | character or NULL. If non-NULL, the levels to retain across both combination and individual levels.  |

**Format**

An object of class AllLevelsSentinel of length 0.

**Value**

a closure suitable for use as a splitting function (splfun) when creating a table layout

**Note**

Analysis or summary functions for which the order matters should never be used within the tabulation framework.

**Examples**

```
library(tibble)
combodf <- tribble(
  ~valname, ~label, ~levelcombo, ~exargs,
  "A_B", "Arms A+B", c("A: Drug X", "B: Placebo"), list(),
  "A_C", "Arms A+C", c("A: Drug X", "C: Combination"), list())

lyt <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM", split_fun = add_combo_levels(combodf)) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
tbl

lyt1 <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM",
    split_fun = add_combo_levels(combodf,
      keep_levels = c("A_B",
        "A_C"))) %>%
  analyze("AGE")

tbl1 <- build_table(lyt1, DM)
tbl1
```

```

smallerDM <- droplevels(subset(DM, SEX %in% c("M", "F") &
                             grepl("^(A|B)", ARM)))
lyt2 <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM", split_fun = add_combo_levels(combodf[1,])) %>%
  split_cols_by("SEX",
               split_fun = add_overall_level("SEX_ALL", "All Genders")) %>%
  analyze("AGE")

lyt3 <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM", split_fun = add_combo_levels(combodf)) %>%
  split_rows_by("SEX",
               split_fun = add_overall_level("SEX_ALL", "All Genders")) %>%
  summarize_row_groups() %>%
  analyze("AGE")

tbl3 <- build_table(lyt3, smallerDM)
tbl3

```

---

sf\_args

*Split Function Arg Conventions*

---

## Description

Split Function Arg Conventions

## Usage

```
sf_args(trim, label, first)
```

## Arguments

|       |   |
|-------|---|
| trim  | logical(1). Should splits corresponding with 0 observations be kept when tabulating.                          |
| label | character(1). A label (not to be confused with the name) for the object/structure.                            |
| first | logical(1). Should the created split level be placed first in the levels (TRUE) or last (FALSE, the default). |

## Value

NULL (this is an argument template dummy function)

## See Also

Other conventions: [compat\\_args\(\)](#), [constr\\_args\(\)](#), [gen\\_args\(\)](#), [lyt\\_args\(\)](#)

---

|                 |                           |
|-----------------|---------------------------|
| simple_analysis | <i>Default tabulation</i> |
|-----------------|---------------------------|

---

## Description

This function is used when [analyze](#) is invoked

## Usage

```
simple_analysis(x, ...)  
  
## S4 method for signature 'numeric'  
simple_analysis(x, ...)  
  
## S4 method for signature 'logical'  
simple_analysis(x, ...)  
  
## S4 method for signature 'factor'  
simple_analysis(x, ...)  
  
## S4 method for signature 'ANY'  
simple_analysis(x, ...)
```

## Arguments

|     |  |
|-----|--|
| x   | the <i>already split</i> data being tabulated for a particular cell/set of cells |
| ... | passed on directly   |

## Details

This function has the following behavior given particular types of inputs:

**numeric** calls [mean](#) on x

**logical** calls [sum](#) on x

**factor** calls [length](#) on x

`in_rows` is called on the resulting value(s).

All other classes of input currently lead to an error.

## Value

an `RowsVerticalSection` object (or `NULL`). The details of this object should be considered an internal implementation detail.

## Author(s)

Gabriel Becker and Adrian Waddell

**Examples**

```
simple_analysis(1:3)
simple_analysis(iris$Species)
simple_analysis(iris$Species == "setosa")
```

---

 sort\_at\_path

*Sorting a Table at a Specific Path*

---

**Description**

Main sorting function to order the substructure of a TableTree at a particular Path in the table tree.

**Usage**

```
sort_at_path(
  tt,
  path,
  scorefun,
  decreasing = NA,
  na.pos = c("omit", "last", "first"),
  .prev_path = character()
)
```

**Arguments**

|            |   |
|------------|---|
| tt         | TableTree (or related class). A TableTree object representing a populated table.  |
| path       | character. A vector path for a position within the structure of a tabletree. Each element represents a subsequent choice amongst the children of the previous choice.   |
| scorefun   | function. Scoring function, should accept the type of children directly under the position at path (either VTableTree, VTableRow, or VTableNodeInfo, which covers both) and return a numeric value to be sorted.              |
| decreasing | logical(1). Should the the scores generated by scorefun be sorted in decreasing order. If unset (the default of NA), it is set to TRUE if the generated scores are numeric and FALSE if they are characters.                  |
| na.pos     | character(1). What should be done with children (sub-trees/rows) with NA scores. Defaults to "omit", which removes them, other allowed values are "last" and "first" which indicate where they should be placed in the order. |
| .prev_path | character. Internal detail, do not set manually.  |

## Details

The path here can include the "wildcard" "\*" as a step, which translates roughly to *any* node/branching element and means that each child at that step will be *separately* sorted based on scorefun and the remaining path entries. This can occur multiple times in a path.

Note that sorting needs a deeper understanding of table structure in rtables. Please consider reading related vignette ([Sorting and Pruning](#)) and explore table structure with useful functions like `table_structure()` and `row_paths_summary()`. It is also very important to understand the difference between "content" rows and "data" rows. The first one analyzes and describes the split variable generally and is generated with `summarize_row_groups()`, while the second one is commonly produced by calling one of the various `analyze()` instances.

Built-in score functions are `cont_n_allcols()` and `cont_n_onecol()`. They are both working with content rows (coming from `summarize_row_groups()`) while a custom score function needs to be used on DataRows. Here, some useful descriptor and accessor functions (coming from related vignette):

- `cell_values()` - Retrieves a named list of a TableRow or TableTree object's values.
- `obj_name()` - Retrieves the name of an object. Note this can differ from the label that is displayed (if any is) when printing.
- `obj_label()` - Retrieves the display label of an object. Note this can differ from the name that appears in the path.
- `content_table()` - Retrieves a TableTree object's content table (which contains its summary rows).
- `tree_children()` - Retrieves a TableTree object's direct children (either subtables, rows or possibly a mix thereof, though that should not happen in practice).

## Value

A TableTree with the same structure as tt with the exception that the requested sorting has been done at path.

## See Also

`cont_n_allcols()` and `cont_n_onecol()`

## Examples

```
# Creating a table to sort

# Function that gives two statistics per table-tree "leaf"
more_analysis_fnc <- function(x) {
  in_rows(
    "median" = median(x),
    "mean" = mean(x),
    .formats = "xx.x"
  )
}

# Main layout of the table
```

```

raw_lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by(
    "RACE",
    split_fun = drop_and_remove_levels("WHITE") # dropping WHITE levels
  ) %>%
  summarize_row_groups() %>%
  split_rows_by("STRATA1") %>%
  summarize_row_groups() %>%
  analyze("AGE", afun = more_analysis_fnc)

# Creating the table and pruning empty and NAs
tbl <- build_table(raw_lyt, DM) %>%
  prune_table()

# Peek at the table structure to understand how it is built
table_structure(tbl)

# Sorting only ASIAN sub-table, or, in other words, sorting STRATA elements for
# the ASIAN group/row-split. This uses content_table() accessor function as it
# is a "ContentRow". In this case, we also base our sorting only on the second column.
sort_at_path(tbl, c("ASIAN", "STRATA1"), cont_n_onecol(2))

# Custom scoring function that is working on "DataRow"s
scorefun <- function(tt) {
  # Here we could use browser()
  sum(unlist(row_values(tt))) # Different accessor function
}
# Sorting mean and median for all the AGE leaves!
sort_at_path(tbl, c("RACE", "*", "STRATA1", "*", "AGE"), scorefun)

```

---

split\_cols\_by

*Declaring a column-split based on levels of a variable*

---

## Description

Will generate children for each subset of a categorical variable

## Usage

```

split_cols_by(
  lyt,
  var,
  labels_var = var,
  split_label = var,
  split_fun = NULL,
  format = NULL,
  nested = TRUE,

```

```

    child_labels = c("default", "visible", "hidden"),
    extra_args = list(),
    ref_group = NULL
)

```

### Arguments

|              |  |
|--------------|--|
| lyt          | layout object pre-data used for tabulation   |
| var          | string, variable name  |
| labels_var   | string, name of variable containing labels to be displayed for the values of var   |
| split_label  | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).  |
| split_fun    | function/NULL. custom splitting function See <a href="#">custom_split_funs</a>   |
| format       | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| nested       | boolean. Should this layout instruction be applied within the existing layout structure <i>if possible</i> (TRUE, the default) or as a new top-level element ('FALSE'). Ignored if it would nest a split underneath analyses, which is not allowed.              |
| child_labels | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.                |
| extra_args   | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function. |
| ref_group    | character(1) or NULL. Level of var which should be considered ref_group/reference  |

### Value

A PreDataTableLayouts object suitable for passing to further layouting functions, and to `build_table`.

### Custom Splitting Function Details

User-defined custom split functions can perform any type of computation on the incoming data provided that they meet the contract for generating 'splits' of the incoming data 'based on' the split object.

Split functions are functions that accept:

**df** data.frame of incoming data to be split

**spl** a Split object. this is largely an internal detail custom functions will not need to worry about, but `obj_name(spl)`, for example, will give the name of the split as it will appear in paths in the resulting table

**vals** Any pre-calculated values. If given non-null values, the values returned should match these. Should be NULL in most cases and can likely be ignored

**labels** Any pre-calculated value labels. Same as above for values

**trim** If TRUE, resulting splits that are empty should be removed

**(Optional) .spl\_context** a data.frame describing previously performed splits which collectively arrived at df

The function must then output a named list with the following elements:

**values** The vector of all values corresponding to the splits of df

**datasplit** a list of data.frames representing the groupings of the actual observations from df.

**labels** a character vector giving a string label for each value listed in the values element above

**(Optional) extras** If present, extra arguments are to be passed to summary and analysis functions whenever they are executed on the corresponding element of datasplit or a subset thereof

One way to generate custom splitting functions is to wrap existing split functions and modify either the incoming data before they are called or their outputs.

Gabriel Becker

### Examples

```
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  analyze(c("AGE", "BMRKR2"))

tbl <- build_table(lyt, ex_adsl)
tbl

# Let's look at the splits in more detail

lyt1 <- basic_table() %>% split_cols_by("ARM")
lyt1

# add an analysis (summary)
lyt2 <- lyt1 %>%
  analyze(c("AGE", "COUNTRY"), afun = list_wrap_x(summary) ,
  format = "xx.xx")
lyt2

tbl2 <- build_table(lyt2, DM)
tbl2

# By default sequentially adding layouts results in nesting
library(dplyr)
DM_MF <- DM %>% filter(SEX %in% c("M", "F")) %>%
  mutate(SEX = droplevels(SEX))
```

```

lyt3 <- basic_table() %>% split_cols_by("ARM") %>%
  split_cols_by("SEX") %>%
  analyze(c("AGE", "COUNTRY"), afun = list_wrap_x(summary),
          format = "xx.xx")
lyt3

tbl3 <- build_table(lyt3, DM_MF)
tbl3

# nested=TRUE vs not
lyt4 <- basic_table() %>% split_cols_by("ARM") %>%
  split_rows_by("SEX", split_fun = drop_split_levels) %>%
  split_rows_by("RACE", split_fun = drop_split_levels) %>%
  analyze("AGE")
lyt4

tbl4 <- build_table(lyt4, DM)
tbl4

lyt5 <- basic_table() %>% split_cols_by("ARM") %>%
  split_rows_by("SEX", split_fun= drop_split_levels) %>%
  analyze("AGE") %>%
  split_rows_by("RACE", nested=FALSE, split_fun = drop_split_levels) %>%
  analyze("AGE")
lyt5

tbl5 <- build_table(lyt5, DM)
tbl5

```

---

split\_cols\_by\_cuts      *Split on static or dynamic cuts of the data*

---

### Description

Create columns (or row splits) based on values (such as quartiles) of var.

### Usage

```

split_cols_by_cuts(
  lyt,
  var,
  cuts,
  cutlabels = NULL,
  split_label = var,
  nested = TRUE,
  cumulative = FALSE
)

```

```
split_rows_by_cuts(  
  lyt,  
  var,  
  cuts,  
  cutlabels = NULL,  
  split_label = var,  
  format = NULL,  
  na_str = NA_character_,  
  nested = TRUE,  
  cumulative = FALSE,  
  label_pos = "hidden",  
  section_div = NA_character_  
)  
  
split_cols_by_cutfun(  
  lyt,  
  var,  
  cutfun = qtile_cuts,  
  cutlabelfun = function(x) NULL,  
  split_label = var,  
  nested = TRUE,  
  extra_args = list(),  
  cumulative = FALSE  
)  
  
split_cols_by_quartiles(  
  lyt,  
  var,  
  split_label = var,  
  nested = TRUE,  
  extra_args = list(),  
  cumulative = FALSE  
)  
  
split_rows_by_quartiles(  
  lyt,  
  var,  
  split_label = var,  
  format = NULL,  
  na_str = NA_character_,  
  nested = TRUE,  
  child_labels = c("default", "visible", "hidden"),  
  extra_args = list(),  
  cumulative = FALSE,  
  indent_mod = 0L,  
  label_pos = "hidden",  
  section_div = NA_character_  
)
```

```

)

  child_labels = c("default", "visible", "hidden"),
  extra_args = list(),
  cumulative = FALSE,
  indent_mod = 0L,
  label_pos = "hidden",
  section_div = NA_character_
)

```

### Arguments

|             |  |
|-------------|--|
| lyt         | layout object pre-data used for tabulation   |
| var         | string, variable name  |
| cuts        | numeric. Cuts to use   |
| cutlabels   | character (or NULL). Labels for the cuts   |
| split_label | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).  |
| nested      | boolean. Should this layout instruction be applied within the existing layout structure <i>if possible</i> (TRUE, the default) or as a new top-level element ('FALSE'). Ignored if it would nest a split underneath analyses, which is not allowed.  |
| cumulative  | logical. Should the cuts be treated as cumulative. Defaults to FALSE   |
| format      | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| na_str      | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".  |
| label_pos   | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| section_div | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |
| cutfun      | function. Function which accepts the full vector of var values and returns cut points to be passed to cut.   |

|              |  |
|--------------|--|
| cutlabelfun  | function. Function which returns either labels for the cuts or NULL when passed the return value of cutfun   |
| extra_args   | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function. |
| child_labels | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.                |
| indent_mod   | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.                 |

### Details

For dynamic cuts, the cut is transformed into a static cut by `build_table` based on the full dataset, before proceeding. Thus even when nested within another split in column/row space, the resulting split will reflect the overall values (e.g., quartiles) in the dataset, NOT the values for subset it is nested under.

### Value

A `PreDataTableLayouts` object suitable for passing to further layouting functions, and to `build_table`.

### Author(s)

Gabriel Becker

### Examples

```
library(dplyr)

# split_cols_by_cuts
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_cols_by_cuts("AGE", split_label = "Age",
                    cuts = c(0, 25, 35, 1000),
                    cutlabels = c("young", "medium", "old")) %>%
  analyze(c("BMRKR2", "STRATA2")) %>%
  append_topleft("counts")

tbl <- build_table(lyt, ex_adsl)
tbl

# split_rows_by_cuts
lyt2 <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by_cuts("AGE", split_label = "Age",
                    cuts = c(0, 25, 35, 1000),
```

```

        cutlabels = c("young", "medium", "old")) %>%
analyze(c("BMRKR2", "STRATA2")) %>%
append_topleft("counts")

tbl2 <- build_table(lyt2, ex_ads1)
tbl2

# split_cols_by_quartiles

lyt3 <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_cols_by_quartiles("AGE", split_label = "Age") %>%
  analyze(c("BMRKR2", "STRATA2")) %>%
  append_topleft("counts")

tbl3 <- build_table(lyt3, ex_ads1)
tbl3

# split_rows_by_quartiles
lyt4 <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM") %>%
  split_rows_by_quartiles("AGE", split_label = "Age") %>%
  analyze("BMRKR2") %>%
  append_topleft(c("Age Quartiles", " Counts BMRKR2"))

tbl4 <- build_table(lyt4, ex_ads1)
tbl4

# split_cols_by_cutfun

---

```
split_cols_by_multivar
```

*Associate Multiple Variables with Columns*

---

### Description

In some cases, the variable to be ultimately analyzed is most naturally defined on a column, not a row basis. When we need columns to reflect different variables entirely, rather than different levels of a single variable, we use `split_cols_by_multivar`

### Usage

```
split_cols_by_multivar(
  lyt,
  vars,
  split_fun = NULL,
  varlabels = vars,
  varnames = NULL,
  nested = TRUE,
  extra_args = list()
)
```

### Arguments

|                         |  |
|-------------------------|--|
| <code>lyt</code>        | layout object pre-data used for tabulation   |
| <code>vars</code>       | character vector. Multiple variable names.   |
| <code>split_fun</code>  | function/NULL. custom splitting function See <a href="#">custom_split_funs</a>   |
| <code>varlabels</code>  | character vector. Labels for vars  |
| <code>varnames</code>   | character vector. Names for vars which will appear in pathing. When vars are all unique this will be the variable names. If not, these will be variable names with suffixes as necessary to enforce uniqueness.  |
| <code>nested</code>     | boolean. Should this layout instruction be applied within the existing layout structure <i>if possible</i> (TRUE, the default) or as a new top-level element ('FALSE). Ignored if it would nest a split underneath analyses, which is not allowed.               |
| <code>extra_args</code> | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function. |

### Value

A `PreDataTableLayouts` object suitable for passing to further layouting functions, and to `build_table`.

**Author(s)**

Gabriel Becker

**See Also**[analyze\\_colvars\(\)](#)**Examples**

```
library(dplyr)
ANL <- DM %>% mutate(value = rnorm(n()), pctdiff = runif(n()))

## toy example where we take the mean of the first variable and the
## count of >.5 for the second.
colfuncs <- list(function(x) in_rows(mean = mean(x), .formats = "xx.x"),
                 function(x) in_rows("# x > 5" = sum(x > .5), .formats = "xx"))

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_cols_by_multivar(c("value", "pctdiff")) %>%
  split_rows_by("RACE", split_label = "ethnicity",
               split_fun = drop_split_levels) %>%
  summarize_row_groups() %>%
  analyze_colvars(afun = colfuncs)
lyt

tbl <- build_table(lyt, ANL)
tbl
```

---

split\_funcs

*Split functions*

---

**Description**

Split functions

**Usage**

```
remove_split_levels(excl)
```

```
keep_split_levels(only, reorder = TRUE)
```

```
drop_split_levels(df, spl, vals = NULL, labels = NULL, trim = FALSE)
```

```
drop_and_remove_levels(excl)
```

```
reorder_split_levels(neworder, newlabels = neworder, drlevels = TRUE)
```

```
trim_levels_in_group(innervar, drop_outlevs = TRUE)
```

### Arguments

|                           |   |
|---------------------------|---|
| <code>excl</code>         | character. Levels to be excluded (they will not be reflected in the resulting table structure regardless of presence in the data).                                      |
| <code>only</code>         | character. Levels to retain (all others will be dropped).   |
| <code>reorder</code>      | logical(1). Should the order of <code>only</code> be used as the order of the children of the split. defaults to TRUE   |
| <code>df</code>           | dataset (data.frame or tibble)  |
| <code>spl</code>          | A Split object defining a partitioning or analysis/tabulation of the data.  |
| <code>vals</code>         | ANY. For internal use only.   |
| <code>labels</code>       | character. Labels to use for the remaining levels instead of the existing ones.   |
| <code>trim</code>         | logical(1). Should splits corresponding with 0 observations be kept when tabulating.  |
| <code>neworder</code>     | character. New order or factor levels.  |
| <code>newlabels</code>    | character. Labels for (new order of) factor levels  |
| <code>drlevels</code>     | logical(1). Should levels in the data which do not appear in <code>neworder</code> be dropped. Defaults to TRUE   |
| <code>innervar</code>     | character(1). Variable whose factor levels should be trimmed (e.g., empty levels dropped) <i>separately within each grouping defined at this point in the structure</i> |
| <code>drop_outlevs</code> | logical(1). Should empty levels in the variable being split on (ie the 'outer' variable, not <code>innervar</code> ) be dropped? Defaults to TRUE                       |

### Value

a closure suitable for use as a splitting function (`splfun`) when creating a table layout

### Custom Splitting Function Details

User-defined custom split functions can perform any type of computation on the incoming data provided that they meet the contract for generating 'splits' of the incoming data 'based on' the split object.

Split functions are functions that accept:

**df** data.frame of incoming data to be split

**spl** a Split object. this is largely an internal detail custom functions will not need to worry about, but `obj_name(spl)`, for example, will give the name of the split as it will appear in paths in the resulting table

**vals** Any pre-calculated values. If given non-null values, the values returned should match these. Should be NULL in most cases and can likely be ignored

**labels** Any pre-calculated value labels. Same as above for values

**trim** If TRUE, resulting splits that are empty should be removed

**(Optional) .spl\_context** a data.frame describing previously performed splits which collectively arrived at df

The function must then output a named list with the following elements:

**values** The vector of all values corresponding to the splits of df

**datasplit** a list of data.frames representing the groupings of the actual observations from df.

**labels** a character vector giving a string label for each value listed in the values element above

**(Optional) extras** If present, extra arguments are to be passed to summary and analysis functions whenever they are executed on the corresponding element of datasplit or a subset thereof

One way to generate custom splitting functions is to wrap existing split functions and modify either the incoming data before they are called or their outputs.

## Examples

```
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("COUNTRY",
               split_fun = remove_split_levels(c("USA", "CAN",
                                                "CHE", "BRA"))) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
tbl

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("COUNTRY",
               split_fun = keep_split_levels(c("USA", "CAN", "BRA"))) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
tbl

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX", split_fun = drop_split_levels) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
tbl

lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX", split_fun = drop_and_remove_levels(c("M", "U"))) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
tbl
```

---

split\_rows\_by

Add Rows according to levels of a variable

---

### Description

Add Rows according to levels of a variable

### Usage

```
split_rows_by(
  lyt,
  var,
  labels_var = var,
  split_label = var,
  split_fun = NULL,
  format = NULL,
  na_str = NA_character_,
  nested = TRUE,
  child_labels = c("default", "visible", "hidden"),
  label_pos = "hidden",
  indent_mod = 0L,
  page_by = FALSE,
  page_prefix = split_label,
  section_div = NA_character_
)
```

### Arguments

|             |  |
|-------------|--|
| lyt         | layout object pre-data used for tabulation   |
| var         | string, variable name  |
| labels_var  | string, name of variable containing labels to be displayed for the values of var   |
| split_label | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).  |
| split_fun   | function/NULL. custom splitting function See <a href="#">custom_split_funs</a>   |
| format      | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.   |
| na_str      | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".  |
| nested      | boolean. Should this layout instruction be applied within the existing layout structure <i>if possible</i> (TRUE, the default) or as a new top-level element ('FALSE). Ignored if it would nest a split underneath analyses, which is not allowed. |

|              |  |
|--------------|--|
| child_labels | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.  |
| label_pos    | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| indent_mod   | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.   |
| page_by      | logical(1). Should pagination be forced between different children resulting from this split.  |
| page_prefix  | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table  |
| section_div  | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |

### Value

A PreDataTableLayouts object suitable for passing to further layouting functions, and to `build_table`.

### Custom Splitting Function Details

User-defined custom split functions can perform any type of computation on the incoming data provided that they meet the contract for generating 'splits' of the incoming data 'based on' the split object.

Split functions are functions that accept:

**df** data.frame of incoming data to be split

**spl** a Split object. this is largely an internal detail custom functions will not need to worry about, but `obj_name(spl)`, for example, will give the name of the split as it will appear in paths in the resulting table

**vals** Any pre-calculated values. If given non-null values, the values returned should match these. Should be NULL in most cases and can likely be ignored

**labels** Any pre-calculated value labels. Same as above for values

**trim** If TRUE, resulting splits that are empty should be removed

**(Optional) .spl\_context** a data.frame describing previously performed splits which collectively arrived at df

The function must then output a named `list` with the following elements:

**values** The vector of all values corresponding to the splits of df

**datasplit** a list of data.frames representing the groupings of the actual observations from df.

**labels** a character vector giving a string label for each value listed in the values element above

**(Optional) extras** If present, extra arguments are to be passed to summary and analysis functions whenever they are executed on the corresponding element of `datasplit` or a subset thereof

One way to generate custom splitting functions is to wrap existing split functions and modify either the incoming data before they are called or their outputs.

### Note

If `var` is a factor with empty unobserved levels and `labels_var` is specified, it must also be a factor with the same number of levels as `var`. Currently the error that occurs when this is not the case is not very informative, but that will change in the future.

tbl
```

---

|             |   |
|-------------|---|
| spl_context | <i>.spl_context within analysis and split functions</i> |
|-------------|---|

---

### Description

.spl\_context within analysis and split functions

### .spl\_context Details

The .spl\_context data.frame gives information about the subsets of data corresponding to the splits within-which the current analyze action is nested. Taken together, these correspond to the path that the resulting (set of) rows the analysis function is creating, although the information is in a slightly different form. Each split (which correspond to groups of rows in the resulting table), as well as the initial 'root' "split", is represented via the following columns:

**split** The name of the split (often the variable being split in the simple case)

**value** The string representation of the value at that split

**full\_parent\_df** a dataframe containing the full data (ie across all columns) corresponding to the path defined by the combination of split and value of this row *and all rows above this row*

**all\_cols\_n** the number of observations corresponding to this row grouping (union of all columns)

**(row-split and analyze contexts only) <1 column for each column in the table structure** These list columns (named the same as names(col\_exprs(tab))) contain logical vectors corresponding to the subset of this row's full\_parent\_df corresponding to that column

**cur\_col\_subset** List column containing logical vectors indicating the subset of that row's full\_parent\_df for the column currently being created by the analysis function

**cur\_col\_n** integer column containing the observation counts for that split

*note Within analysis functions that accept .spl\_context, the all\_cols\_n and cur\_col\_n columns of the dataframe will contain the 'true' observation counts corresponding to the row-group and row-group x column subsets of the data. These numbers will not, and currently cannot, reflect alternate column observation counts provided by the alt\_counts\_df, col\_counts or col\_total arguments to build\_table*

---

|                          |  |
|--------------------------|--|
| spl_context_to_disp_path | <i>Translate spl_context to Path for display in error messages</i> |
|--------------------------|--|

---

### Description

Translate spl\_context to Path for display in error messages

### Usage

```
spl_context_to_disp_path(ctx)
```

**Arguments**

ctx                    data.frame. The spl\_context data.frame where the error occurred

**Value**

A character string containing a description of the row path corresponding to the ctx

---

|              |   |
|--------------|---|
| spl_variable | <i>Variable Associated With a Split</i> |
|--------------|---|

---

**Description**

This function is intended for use when writing custom splitting logic. In cases where the split is associated with a single variable, the name of that variable will be returned. At time of writing this includes splits generated via the [split\\_rows\\_by](#), [split\\_cols\\_by](#), [split\\_rows\\_by\\_cuts](#), [split\\_cols\\_by\\_cuts](#), [split\\_rows\\_by\\_cutfun](#), and [split\\_cols\\_by\\_cutfun](#) layout directives.

**Usage**

```
spl_variable(spl)

## S4 method for signature 'VarLevelSplit'
spl_variable(spl)

## S4 method for signature 'VarDynCutSplit'
spl_variable(spl)

## S4 method for signature 'VarStaticCutSplit'
spl_variable(spl)

## S4 method for signature 'Split'
spl_variable(spl)
```

**Arguments**

spl                    Split. The split object

**Value**

for splits with a single variable associated with them, the split, for others, an error is raised.

**See Also**

[make\\_split\\_fun](#)

---

|                |                       |
|----------------|-----------------------|
| summarize_rows | <i>summarize_rows</i> |
|----------------|-----------------------|

---

**Description**

summarize\_rows is deprecated in favor of make\_row\_df.

**Usage**

```
summarize_rows(obj)
```

**Arguments**

obj           VTableTree.

**Value**

A data.frame summarizing the rows in obj.

---

|                      |  |
|----------------------|--|
| summarize_row_groups | <i>Add a content row of summary counts</i> |
|----------------------|--|

---

**Description**

Add a content row of summary counts

**Usage**

```
summarize_row_groups(  
  lyt,  
  var = "",  
  label_fstr = "%s",  
  format = "xx (xx.x%)",  
  na_str = "-",  
  cfun = NULL,  
  indent_mod = 0L,  
  extra_args = list()  
)
```

**Arguments**

|            |   |
|------------|---|
| lyt        | layout object pre-data used for tabulation  |
| var        | string, variable name   |
| label_fstr | string. An sprintf style format string containing. For non-comparison splits, it can contain up to one "%s" which takes the current split value and generates the row/column label. Comparison-based splits it can contain up to two "%s".                            |
| format     | FormatSpec. Format associated with this split. Formats can be declared via strings ("xx.x") or function. In cases such as analyze calls, they can character vectors or lists of functions.  |
| na_str     | character(1). String that should be displayed when the value of x is missing. Defaults to "NA".   |
| cfun       | list/function/NULL. tabulation function(s) for creating content rows. Must accept x or df as first parameter. Must accept labelstr as the second argument. Can optionally accept all optional arguments accepted by analysis functions. See <a href="#">analyze</a> . |
| indent_mod | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.                      |
| extra_args | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function.      |

**Details**

If format expects 1 value (i.e. it is specified as a format string and xx appears for two values (i.e. xx appears twice in the format string) or is specified as a function, then both raw and percent of column total counts are calculated. If format is a format string where xx appears only one time, only raw counts are used.

cfun must accept x or df as its first argument. For the df argument cfun will receive the subset data.frame corresponding with the row- and column-splitting for the cell being calculated. Must accept labelstr as the second parameter, which accepts the label of the level of the parent split currently being summarized. Can additionally take any optional argument supported by analysis functions. (see [analyze](#)).

**Value**

A PreDataTableLayouts object suitable for passing to further layouting functions, and to build\_table.

**Author(s)**

Gabriel Becker

**Examples**

```

DM2 <- subset(DM, COUNTRY %in% c("USA", "CAN", "CHN"))

lyt <- basic_table() %>% split_cols_by("ARM") %>%
  split_rows_by("COUNTRY", split_fun = drop_split_levels) %>%
  summarize_row_groups(label_fstr = "%s (n)") %>%
  analyze("AGE", afun = list_wrap_x(summary) , format = "xx.xx")
lyt

tbl <- build_table(lyt, DM2)
tbl

row_paths_summary(tbl) # summary count is a content table

## use a cfun and extra_args to customize summarization
## behavior
sfun <- function(x, labelstr, trim) {
  in_rows(
    c(mean(x, trim = trim), trim),
    .formats = "xx.x (xx.x%)",
    .labels = sprintf("%s (Trimmed mean and trim %%)",
                      labelstr)
  )
}

lyt2 <- basic_table(show_colcounts = TRUE) %>%
  split_cols_by("ARM") %>%
  split_rows_by("COUNTRY", split_fun = drop_split_levels) %>%
  summarize_row_groups("AGE", cfun = sfun,
                      extra_args = list(trim = .2)) %>%
  analyze("AGE", afun = list_wrap_x(summary) , format = "xx.xx") %>%
  append_topleft(c("Country", " Age"))

tbl2 <- build_table(lyt2, DM2)
tbl2

```

---

table\_shell

*Table shells*

---

**Description**

A table shell is a rendering of the table which maintains the structure, but does not display the values, rather displaying the formatting instructions for each cell.

**Usage**

```
table_shell(
  tt,
  widths = NULL,
  col_gap = 3,
  hsep = default_hsep(),
  tf_wrap = FALSE,
  max_width = NULL
)
```

```
table_shell_str(
  tt,
  widths = NULL,
  col_gap = 3,
  hsep = default_hsep(),
  tf_wrap = FALSE,
  max_width = NULL
)
```

**Arguments**

|           |  |
|-----------|--|
| tt        | TableTree (or related class). A TableTree object representing a populated table.   |
| widths    | widths of row.name and columns   |
| col_gap   | gap between columns  |
| hsep      | character to create line separator   |
| tf_wrap   | logical(1). Should the texts for title, subtitle, and footnotes be wrapped?  |
| max_width | integer(1), character(1) or NULL. Width that title and footer (including footnotes) materials should be word-wrapped to. If NULL, it is set to the current print width of the session (getOption("width")). If set to "auto", the width of the table (plus any table inset) is used. Ignored completely if tf_wrap is FALSE. |

**Value**

for table\_shell\_str the string representing the table shell, for table\_shell, NULL, as the function is called for the side effect of printing the shell to the console

**Examples**

```
library(dplyr)

iris2 <- iris %>%
  group_by(Species) %>%
  mutate(group = as.factor(rep_len(c("a", "b"), length.out = n())) %>%
  ungroup()

lyt <- basic_table() %>%
  split_cols_by("Species") %>%
```

```

split_cols_by("group") %>%
analyze(c("Sepal.Length", "Petal.Width"), afun = list_wrap_x(summary) , format = "xx.xx")

tbl <- build_table(lyt, iris2)
table_shell(tbl)

```

---

|                 |                        |
|-----------------|------------------------|
| table_structure | <i>Summarize Table</i> |
|-----------------|------------------------|

---

## Description

Summarize Table

## Usage

```
table_structure(x, detail = c("subtable", "row"))
```

## Arguments

|        |                        |
|--------|------------------------|
| x      | a table object         |
| detail | either row or subtable |

## Value

currently no return value. Called for the side-effect of printing a row- or subtable-structure summary of x.

## Examples

```

library(dplyr)

iris2 <- iris %>%
  group_by(Species) %>%
  mutate(group = as.factor(rep_len(c("a", "b"), length.out = n())) %>%
  ungroup()

lyt <- basic_table() %>%
  split_cols_by("Species") %>%
  split_cols_by("group") %>%
  analyze(c("Sepal.Length", "Petal.Width"), afun = list_wrap_x(summary),
          format = "xx.xx")

tbl <- build_table(lyt, iris2)
tbl

row_paths(tbl)

table_structure(tbl)

table_structure(tbl, detail = "row")

```

---

|          |   |
|----------|---|
| top_left | <i>Top Left Material (Experimental)</i> |
|----------|---|

---

### Description

A TableTree object can have *top left material* which is a sequence of strings which are printed in the area of the table between the column header display and the label of the first row. These functions access and modify that material.

### Usage

```
top_left(obj)

## S4 method for signature 'VTableTree'
top_left(obj)

## S4 method for signature 'InstantiatedColumnInfo'
top_left(obj)

## S4 method for signature 'PreDataTableLayouts'
top_left(obj)

top_left(obj) <- value

## S4 replacement method for signature 'VTableTree'
top_left(obj) <- value

## S4 replacement method for signature 'InstantiatedColumnInfo'
top_left(obj) <- value

## S4 replacement method for signature 'PreDataTableLayouts'
top_left(obj) <- value
```

### Arguments

|       |  |
|-------|--|
| obj   | ANY. The object for the accessor to access or modify |
| value | The new value  |

### Value

A character vector representing the top-left material of obj (or obj after modification, in the case of the setter).

---

|          |   |
|----------|---|
| tostring | <i>Convert an rtable object to a string</i> |
|----------|---|

---

### Description

Transform a complex object into a string representation ready to be printed or written to a plain-text file

### Usage

```
## S4 method for signature 'VTableTree'
toString(
  x,
  widths = NULL,
  col_gap = 3,
  hsep = horizontal_sep(x),
  indent_size = 2,
  tf_wrap = FALSE,
  max_width = NULL
)
```

### Arguments

|             |  |
|-------------|--|
| x           | table object   |
| widths      | widths of row.name and columns   |
| col_gap     | gap between columns  |
| hsep        | character to create line separator   |
| indent_size | numeric(1). Number of spaces to use per indent level. Defaults to 2  |
| tf_wrap     | logical(1). Should the texts for title, subtitle, and footnotes be wrapped?  |
| max_width   | integer(1), character(1) or NULL. Width that title and footer (including footnotes) materials should be word-wrapped to. If NULL, it is set to the current print width of the session ( <code>getOption("width")</code> ). If set to "auto", the width of the table (plus any table inset) is used. Ignored completely if <code>tf_wrap</code> is FALSE. |

### Details

Manual insertion of newlines is not supported when `tf_wrap` is on and will result in a warning and undefined wrapping behavior. Passing vectors of already split strings remains supported, however in this case each string is word-wrapped separately with the behavior described above.

### Value

a string representation of `x` as it appears when printed.

**Examples**

```
library(dplyr)

iris2 <- iris %>%
  group_by(Species) %>%
  mutate(group = as.factor(rep_len(c("a", "b"), length.out = n()))) %>%
  ungroup()

lyt <- basic_table() %>%
  split_cols_by("Species") %>%
  split_cols_by("group") %>%
  analyze(c("Sepal.Length", "Petal.Width"), afun = list_wrap_x(summary) , format = "xx.xx")

tbl <- build_table(lyt, iris2)

cat(toString(tbl, col_gap = 3))
```

---

tree\_children

*Retrieve or set the direct children of a Tree-style object*

---

**Description**

Retrieve or set the direct children of a Tree-style object

**Usage**

```
tree_children(x)
```

```
tree_children(x) <- value
```

**Arguments**

|       |                                 |
|-------|---------------------------------|
| x     | An object with a Tree structure |
| value | New list of children.           |

**Value**

List of direct children of x

---

trim\_levels\_in\_facets *Trim Levels of Another Variable From Each Facet (Postprocessing split step)*

---

**Description**

Trim Levels of Another Variable From Each Facet (Postprocessing split step)

**Usage**

```
trim_levels_in_facets(innervar)
```

**Arguments**

innervar            character. The variable(s) to trim (remove unobserved levels) independently within each facet.

**Value**

a function suitable for use in the pre (list) argument of make\_split\_fun

**See Also**

make\_split\_fun

Other make\_custom\_split: [add\\_combo\\_facet\(\)](#), [drop\\_facet\\_levels\(\)](#), [make\\_split\\_fun\(\)](#), [make\\_split\\_result\(\)](#)

---

trim\_levels\_to\_map    *Trim Levels to map*

---

**Description**

This split function constructor creates a split function which trims levels of a variable to reflect restrictions on the possible combinations of two or more variables which are split by (along the same axis) within a layout.

**Usage**

```
trim_levels_to_map(map = NULL)
```

**Arguments**

map                data.frame. A data.frame defining allowed combinations of variables. Any combination at the level of this split not present in the map will be removed from the data, both for the variable being split and those present in the data but not associated with this split or any parents of it.

**Details**

When splitting occurs, the map is subset to the values of all previously performed splits. The levels of the variable being split are then pruned to only those still present within this subset of the map representing the current hierarchical splitting context.

Splitting is then performed via the [keep\\_split\\_levels](#) split function.

Each resulting element of the partition is then further trimmed by pruning values of any remaining variables specified in the map to those values allowed under the combination of the previous and current split.

**Value**

a fun

**See Also**

[trim\\_levels\\_in\\_group\(\)](#)

**Examples**

```
map <- data.frame(
  LBCAT = c("CHEMISTRY", "CHEMISTRY", "CHEMISTRY", "IMMUNOLOGY"),
  PARAMCD = c("ALT", "CRP", "CRP", "IGA"),
  ANRIND = c("LOW", "LOW", "HIGH", "HIGH"),
  stringsAsFactors = FALSE
)

lyt <- basic_table() %>%
  split_rows_by("LBCAT") %>%
  split_rows_by("PARAMCD", split_fun = trim_levels_to_map(map = map)) %>%
  analyze("ANRIND")
tbl <- build_table(lyt, ex_adlb)
```

---

trim\_rows

*Trim rows from a populated table without regard for table structure*

---

**Description**

Trim rows from a populated table without regard for table structure

**Usage**

```
trim_rows(tt, criteria = all_zero_or_na)
```

**Arguments**

**tt** TableTree (or related class). A TableTree object representing a populated table.

**criteria** function. Function which takes a TableRow object and returns TRUE if that row should be removed. Defaults to [all\\_zero\\_or\\_na](#)

**Details**

This function will be deprecated in the future in favor of the more elegant and versatile [prune\\_table\(\)](#) function which can perform the same function as `trim_rows()` but is more powerful as it takes table structure into account.

**Value**

The table with rows that have only NA or 0 cell values removed

**Note**

Visible LabelRows are including in this trimming, which can lead to either all label rows being trimmed or label rows remaining when all data rows have been trimmed, depending on what criteria returns when called on a LabelRow object. To avoid this, use the structurally-aware [prune\\_table](#) machinery instead.

**See Also**

[prune\\_table\(\)](#)

**Examples**

```
adsl <- ex_adsl
levels(adsl$SEX) <- c(levels(ex_adsl$SEX), "OTHER")

tbl_to_trim <- basic_table() %>%
  analyze("BMRKR1") %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX") %>%
  summarize_row_groups() %>%
  split_rows_by("STRATA1") %>%
  summarize_row_groups() %>%
  analyze("AGE") %>%
  build_table(adsl)

tbl_to_trim %>% trim_rows()

tbl_to_trim %>% trim_rows(all_zero)
```

---

 trim\_zero\_rows

*Trim Zero Rows*

---

**Description**

Trim Zero Rows

**Usage**

```
trim_zero_rows(tbl)
```

**Arguments**

tbl                    table object

**Value**

an rtable object

---

|            |  |
|------------|--|
| tt_at_path | <i>Get or set table elements at specified path</i> |
|------------|--|

---

**Description**

Get or set table elements at specified path

**Usage**

```
tt_at_path(tt, path, ...)
tt_at_path(tt, path, ...) <- value
```

**Arguments**

tt                    TableTree (or related class). A TableTree object representing a populated table.

path                  character. A vector path for a position within the structure of a tabletree. Each element represents a subsequent choice amongst the children of the previous choice.

...                   unused.

value                 The new value

**Note**

Setting NULL at a defined path removes the corresponding sub table.

**Examples**

```
# Accessing sub table.
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX") %>%
  split_rows_by("BMRKR2") %>%
  analyze("AGE")

tbl <- build_table(lyt, ex_adsl) %>% prune_table()
```

```

sub_tbl <- tt_at_path(tbl, path = c("SEX", "F", "BMRKR2"))

# Removing sub table.
tbl2 <- tbl
tt_at_path(tbl2, path = c("SEX", "F")) <- NULL
tbl2

# Setting sub table.
lyt3 <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_rows_by("SEX") %>%
  analyze("BMRKR2")

tbl3 <- build_table(lyt3, ex_ads1) %>% prune_table()

tt_at_path(tbl3, path = c("SEX", "F", "BMRKR2")) <- sub_tbl
tbl3

```

---

tt\_to\_flextable

*Create a FlexTable object representing an rtables TableTree*

---

## Description

Create a FlexTable object representing an rtables TableTree

## Usage

```

tt_to_flextable(
  tt,
  paginate = FALSE,
  lpp = NULL,
  cpp = NULL,
  ...,
  colwidths = propose_column_widths(matrix_form(tt, indent_rownames = TRUE)),
  tf_wrap = !is.null(cpp),
  max_width = cpp,
  total_width = 10
)

```

## Arguments

|          |   |
|----------|---|
| tt       | TableTree (or related class). A TableTree object representing a populated table.          |
| paginate | logical(1). Should tt be paginated and exported as multiple flextables. Defaults to FALSE |
| lpp      | numeric. Maximum lines per page including (re)printed header and context rows             |

|             |  |
|-------------|--|
| cpp         | numeric(1) or NULL. Width (in characters) of the pages for horizontal pagination. NA (the default) indicates cpp should be inferred from the page size; NULL indicates no horizontal pagination should be done regardless of page size.  |
| ...         | Passed on to methods or tabulation functions.  |
| colwidths   | numeric vector. Column widths for use with vertical pagination.  |
| tf_wrap     | logical(1). Should the texts for title, subtitle, and footnotes be wrapped?  |
| max_width   | integer(1), character(1) or NULL. Width that title and footer (including footnotes) materials should be word-wrapped to. If NULL, it is set to the current print width of the session ( <code>getOption("width")</code> ). If set to "auto", the width of the table (plus any table inset) is used. Ignored completely if <code>tf_wrap</code> is FALSE. |
| total_width | numeric(1). Total width in inches for the resulting flextable(s). Defaults to 5.   |

**Value**

a flextable object

**Examples**

```
analysisfun <- function(x, ...) {
  in_rows(row1 = 5,
          row2 = c(1, 2),
          .row_footnotes = list(row1 = "row 1 - row footnote"),
          .cell_footnotes = list(row2 = "row 2 - cell footnote"))
}

lyt <- basic_table(title = "Title says Whaaaaat", subtitles = "Oh, ok.",
                  main_footer = "ha HA! Footer!") %>%
split_cols_by("ARM") %>%
analyze("AGE", afun = analysisfun)

tbl <- build_table(lyt, ex_adsl)
ft <- tt_to_flextable(tbl)
ft
```

---

update\_ref\_indexing     *Update footnote indexes on a built table*

---

**Description**

Re-indexes footnotes within a built table

**Usage**

```
update_ref_indexing(tt)
```

**Arguments**

tt                    TableTree (or related class). A TableTree object representing a populated table.

**Details**

After adding or removing referential footnotes manually, or after subsetting a table, the reference indexes (ie the number associated with specific footnotes) may be incorrect. This function recalculates these based on the full table.

**Note**

In the future this should not generally need to be called manually.

---

|               |                      |
|---------------|----------------------|
| value_formats | <i>Value Formats</i> |
|---------------|----------------------|

---

**Description**

Returns a matrix of formats for the cells in a table

**Usage**

```
value_formats(obj, default = obj_format(obj))

## S4 method for signature 'ANY'
value_formats(obj, default = obj_format(obj))

## S4 method for signature 'TableRow'
value_formats(obj, default = obj_format(obj))

## S4 method for signature 'LabelRow'
value_formats(obj, default = obj_format(obj))

## S4 method for signature 'VTableTree'
value_formats(obj, default = obj_format(obj))
```

**Arguments**

obj                    A table or row object.  
 default                FormatSpec.

**Value**

Matrix (storage mode list) containing the effective format for each cell position in the table (including 'virtual' cells implied by label rows, whose formats are always NULL)

**Examples**

```
lyt <- basic_table() %>%
  split_rows_by("RACE", split_fun = keep_split_levels(c("ASIAN", "WHITE"))) %>%
  analyze("AGE")

tbl <- build_table(lyt, DM)
value_formats(tbl)
```

---

VarLevelSplit-class     *Split on levels within a variable*

---

**Description**

Split on levels within a variable

**Usage**

```
VarLevelSplit(
  var,
  split_label,
  labels_var = NULL,
  cfun = NULL,
  cformat = NULL,
  cna_str = NA_character_,
  split_fun = NULL,
  split_format = NULL,
  split_na_str = NA_character_,
  valorder = NULL,
  split_name = var,
  child_labels = c("default", "visible", "hidden"),
  extra_args = list(),
  indent_mod = 0L,
  label_pos = c("topleft", "hidden", "visible"),
  cindent_mod = 0L,
  cvar = "",
  cextra_args = list(),
  page_prefix = NA_character_,
  section_div = NA_character_
)

VarLevWBaselineSplit(
  var,
  ref_group,
  labels_var = var,
  split_label,
  split_fun = NULL,
```

```

label_fstr = "%s - %s",
cfun = NULL,
cformat = NULL,
cna_str = NA_character_,
cvar = "",
split_format = NULL,
split_na_str = NA_character_,
valorder = NULL,
split_name = var,
extra_args = list()
)

```

### Arguments

|                           |  |
|---------------------------|--|
| <code>var</code>          | string, variable name  |
| <code>split_label</code>  | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).  |
| <code>labels_var</code>   | string, name of variable containing labels to be displayed for the values of <code>var</code>  |
| <code>cfun</code>         | list/function/NULL. tabulation function(s) for creating content rows. Must accept <code>x</code> or <code>df</code> as first parameter. Must accept <code>labelstr</code> as the second argument. Can optionally accept all optional arguments accepted by analysis functions. See <a href="#">analyze</a> .                         |
| <code>cformat</code>      | format spec. Format for content rows   |
| <code>cna_str</code>      | character. NA string for use with <code>cformat</code> for content table.  |
| <code>split_fun</code>    | function/NULL. custom splitting function See <a href="#">custom_split_funs</a>   |
| <code>split_format</code> | FormatSpec. Default format associated with the split being created.  |
| <code>split_na_str</code> | character. NA string vector for use with <code>split_format</code> .   |
| <code>valorder</code>     | character vector. Order that the split children should appear in resulting table.  |
| <code>split_name</code>   | string. Name associated with this split (for pathing, etc)   |
| <code>child_labels</code> | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.  |
| <code>extra_args</code>   | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function.   |
| <code>indent_mod</code>   | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.   |
| <code>label_pos</code>    | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |

|                          |  |
|--------------------------|--|
| <code>cindent_mod</code> | numeric(1). The indent modifier for the content tables generated by this split.  |
| <code>cvar</code>        | character(1). The variable, if any, which the content function should accept. Defaults to NA.  |
| <code>cextra_args</code> | list. Extra arguments to be passed to the content function when tabulating row group summaries.  |
| <code>page_prefix</code> | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table  |
| <code>section_div</code> | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or <code>NA_character_</code> (the default) for no section divider.   |
| <code>ref_group</code>   | character. Value of <code>var</code> to be taken as the <code>ref_group/control</code> to be compared against.   |
| <code>label_fstr</code>  | string. An <code>sprintf</code> style format string containing. For non-comparison splits, it can contain up to one <code>"%s"</code> which takes the current split value and generates the row/column label. Comparison-based splits it can contain up to two <code>"%s"</code> . |

**Value**

a `VarLevelSplit` object.

**Author(s)**

Gabriel Becker

---

`VarStaticCutSplit-class`

*Splits for cutting by values of a numeric variable*

---

**Description**

Splits for cutting by values of a numeric variable

Create static cut or static cumulative cut split

**Usage**

```
make_static_cut_split(
  var,
  split_label,
  cuts,
  cutlabels = NULL,
  cfun = NULL,
  cformat = NULL,
  cna_str = NA_character_,
  split_format = NULL,
  split_na_str = NA_character_,
```

```

split_name = var,
child_labels = c("default", "visible", "hidden"),
extra_args = list(),
indent_mod = 0L,
cindent_mod = 0L,
cvar = "",
cextra_args = list(),
label_pos = "visible",
cumulative = FALSE,
page_prefix = NA_character_,
section_div = NA_character_
)

```

```

VarDynCutSplit(
  var,
  split_label,
  cutfun,
  cutlabelfun = function(x) NULL,
  cfun = NULL,
  cformat = NULL,
  cna_str = NA_character_,
  split_format = NULL,
  split_na_str = NA_character_,
  split_name = var,
  child_labels = c("default", "visible", "hidden"),
  extra_args = list(),
  cumulative = FALSE,
  indent_mod = 0L,
  cindent_mod = 0L,
  cvar = "",
  cextra_args = list(),
  label_pos = "visible",
  page_prefix = NA_character_,
  section_div = NA_character_
)

```

### Arguments

|             |   |
|-------------|---|
| var         | string, variable name   |
| split_label | string. Label string to be associated with the table generated by the split. Not to be confused with labels assigned to each child (which are based on the data and type of split during tabulation).   |
| cuts        | numeric. Cuts to use  |
| cutlabels   | character (or NULL). Labels for the cuts  |
| cfun        | list/function/NULL. tabulation function(s) for creating content rows. Must accept x or df as first parameter. Must accept labelstr as the second argument. Can optionally accept all optional arguments accepted by analysis functions. See <a href="#">analyze</a> . |

|              |  |
|--------------|--|
| cformat      | format spec. Format for content rows   |
| cna_str      | character. NA string for use with cformat for content table.   |
| split_format | FormatSpec. Default format associated with the split being created.  |
| split_na_str | character. NA string vector for use with split_format.   |
| split_name   | string. Name associated with this split (for pathing, etc)   |
| child_labels | string. One of "default", "visible", "hidden". What should the display behavior be for the labels (ie label rows) of the children of this split. Defaults to "default" which flags the label row as visible only if the child has 0 content rows.  |
| extra_args   | list. Extra arguments to be passed to the tabulation function. Element position in the list corresponds to the children of this split. Named elements in the child-specific lists are ignored if they do not match a formal argument of the tabulation function.   |
| indent_mod   | numeric. Modifier for the default indent position for the structure created by this function(subtable, content table, or row) <i>and all of that structure's children</i> . Defaults to 0, which corresponds to the unmodified default behavior.   |
| cindent_mod  | numeric(1). The indent modifier for the content tables generated by this split.  |
| cvar         | character(1). The variable, if any, which the content function should accept. Defaults to NA.  |
| cextra_args  | list. Extra arguments to be passed to the content function when tabulating row group summaries.  |
| label_pos    | character(1). Location the variable label should be displayed, Accepts hidden (default for non-analyze row splits), visible, topleft, and - for analyze splits only - default. For analyze calls, default indicates that the variable should be visible if and only if multiple variables are analyzed at the same level of nesting. |
| cumulative   | logical. Should the cuts be treated as cumulative. Defaults to FALSE   |
| page_prefix  | character(1). Prefix, to be appended with the split value, when forcing pagination between the children of this split/table  |
| section_div  | character(1). String which should be repeated as a section divider after each group defined by this split instruction, or NA_character_ (the default) for no section divider.  |
| cutfun       | function. Function which accepts the <i>full vector</i> of var values and returns cut points to be used (via cut) when splitting data during tabulation  |
| cutlabelfun  | function. Function which returns either labels for the cuts or NULL when passed the return value of cutfun   |

**Value**

a VarStaticCutSplit, CumulativeCutSplit object for `make_static_cut_split`, or a VarDynCutSplit object for `VarDynCutSplit()`

---

|                |   |
|----------------|---|
| vars_in_layout | <i>List Variables required by a pre-data table layout</i> |
|----------------|---|

---

**Description**

List Variables required by a pre-data table layout

**Usage**

```
vars_in_layout(lyt)

## S4 method for signature 'PreDataTableLayouts'
vars_in_layout(lyt)

## S4 method for signature 'PreDataAxisLayout'
vars_in_layout(lyt)

## S4 method for signature 'SplitVector'
vars_in_layout(lyt)

## S4 method for signature 'Split'
vars_in_layout(lyt)

## S4 method for signature 'CompoundSplit'
vars_in_layout(lyt)

## S4 method for signature 'ManualSplit'
vars_in_layout(lyt)
```

**Arguments**

lyt                    The Layout (or a component thereof)

**Details**

This will walk the layout declaration and return a vector of the names of the unique variables that are used in any of the following ways:

- Variable being split on (directly or via cuts)
- Element of a Multi-variable column split
- Content variable
- Value-label variable

**Value**

A character vector containing the unique variables explicitly used in the layout (see Notes).

**Note**

This function will not detect dependencies implicit in analysis or summary functions which accept `x` or `df` and then rely on the existence of particular variables not being split on/ analyzed.

The order these variable names appear within the return vector is undefined and should not be relied upon.

**Examples**

```
lyt <- basic_table() %>%
  split_cols_by("ARM") %>%
  split_cols_by("SEX") %>%
  summarize_row_groups(label_fstr = "Overall (N)") %>%
  split_rows_by("RACE", split_label = "Ethnicity", labels_var = "ethn_lab",
               split_fun = drop_split_levels) %>%
  summarize_row_groups("RACE", label_fstr = "%s (n)") %>%
  analyze("AGE", var_labels = "Age", afun = mean, format = "xx.xx")

vars_in_layout(lyt)
```

---

|        |  |
|--------|--|
| Viewer | <i>Display an <code>rtable</code> object in the Viewer pane in RStudio or in a browser</i> |
|--------|--|

---

**Description**

The table will be displayed using the bootstrap styling for tables.

**Usage**

```
Viewer(x, y = NULL, row.names.bold = FALSE, ...)
```

**Arguments**

|                             |  |
|-----------------------------|--|
| <code>x</code>              | object of class <code>rtable</code> or <code>shiny.tag</code> (defined in <code>htmltools</code> ) |
| <code>y</code>              | optional second argument of same type as <code>x</code>  |
| <code>row.names.bold</code> | <code>row.names.bold</code> boolean, make rownames bold  |
| <code>...</code>            | arguments passed to <code>as_html</code>   |

**Value**

not meaningful. Called for the side effect of opening a browser or viewer pane.

**Examples**

```
if(interactive()) {
  s15 <- factor(iris$Sepal.Length > 5, levels = c(TRUE, FALSE),
    labels = c("S.L > 5", "S.L <= 5"))

  df <- cbind(iris, s15 = s15)

  lyt <- basic_table() %>%
    split_cols_by("s15") %>%
    analyze("Sepal.Length")

  tbl <- build_table(lyt, df)

  Viewer(tbl)
  Viewer(tbl, tbl)

  tbl2 <- htmltools::tags$div(
    class = "table-responsive",
    as_html(tbl, class_table = "table")
  )

  Viewer(tbl, tbl2)
}
```
